Technical Support

Technical Support maintains support centers globally. Technical Support's primary role is to respond to specific queries about product features and functionality. The Technical Support group also creates content for our online Knowledge Base. The Technical Support group works collaboratively with the other functional areas within the company to answer your questions in a timely fashion.

Our support offerings include the following:

- A range of support options that give you the flexibility to select the right amount of service for any size organization
- Telephone and/or Web-based support that provides rapid response and up-to-the-minute information
- Upgrade assurance that delivers software upgrades
- Global support purchased on a regional business hours or 24 hours a day, 7 days a week basis
- Premium service offerings that include Account Management Services

For information about our support offerings, you can visit our website at the following URL:

www.veritas.com/support

All support services will be delivered in accordance with your support agreement and the then-current enterprise technical support policy.

Contacting Technical Support

Customers with a current support agreement may access Technical Support information at the following URL:

www.veritas.com/support

Before contacting Technical Support, make sure you have satisfied the system requirements that are listed in your product documentation. Also, you should be at the computer on which the problem occurred, in case it is necessary to replicate the problem.

When you contact Technical Support, please have the following information available:

- Product release level
- Hardware information
- Available memory, disk space, and NIC information

- Operating system
- Version and patch level
- Network topology
- Router, gateway, and IP address information
- Problem description:
 - Error messages and log files
 - Troubleshooting that was performed before contacting Technical Support
 - Recent software configuration changes and network changes

Licensing and registration

If your product requires registration or a license key, access our technical support Web page at the following URL:

www.veritas.com/support

Customer service

Customer service information is available at the following URL:

www.veritas.com/support

Customer Service is available to assist with non-technical questions, such as the following types of issues:

- Questions regarding product licensing or serialization
- Product registration updates, such as address or name changes
- General product information (features, language availability, local dealers)
- Latest information about product updates and upgrades
- Information about upgrade assurance and support contracts
- Advice about technical support options
- Nontechnical presales questions
- Issues that are related to CD-ROMs, DVDs, or manuals

Support agreement resources

If you want to contact us regarding an existing support agreement, please contact the support agreement administration team for your region as follows:

Worldwide (except Japan)

Chapter

Understanding DMP

This chapter includes the following topics:

- About Dynamic Multi-Pathing (DMP)
- How DMP works
- Multiple paths to disk arrays
- Device discovery
- Disk devices
- Disk device naming in DMP

About Dynamic Multi-Pathing (DMP)

Dynamic Multi-Pathing (DMP) provides multi-pathing functionality for the operating system native devices that are configured on the system. DMP creates DMP metadevices (also known as DMP nodes) to represent all the device paths to the same physical LUN.

DMP is also available as a standalone product, which extends DMP metadevices to support the OS native logical volume manager (LVM). You can create LVM volumes and volume groups on DMP metadevices.

DMP supports the LVM volume devices that are used as the paging devices.

Veritas Volume Manager (VxVM) volumes and disk groups can co-exist with LVM volumes and volume groups. But, each device can only support one of the types. If a disk has a VxVM label, then the disk is not available to LVM. Similarly, if a disk is in use by LVM, then the disk is not available to VxVM.

How DMP works

Dynamic Multi-Pathing (DMP) provides greater availability, reliability, and performance by using the path failover feature and the load balancing feature. These features are available for multiported disk arrays from various vendors.

Disk arrays can be connected to host systems through multiple paths. To detect the various paths to a disk, DMP uses a mechanism that is specific to each supported array. DMP can also differentiate between different enclosures of a supported array that are connected to the same host system.

The multi-pathing policy that DMP uses depends on the characteristics of the disk array.

DMP supports the following standard array types:

Array type	Description
Active/Active (A/A)	Allows several paths to be used concurrently for I/O. Such arrays allow DMP to provide greater I/O throughput by balancing the I/O load uniformly across the multiple paths to the LUNs. In the event that one path fails, DMP automatically routes I/O over the other available paths.
Asymmetric Active/Active (A/A-A)	A/A-A or Asymmetric Active/Active arrays can be accessed through secondary storage paths with little performance degradation. The behavior is similar to ALUA, except that it does not support the SCSI commands that an ALUA array supports.
Asymmetric Logical Unit Access (ALUA)	DMP supports all variants of ALUA.

Table 1-1

Array type	Description
Active/Passive (A/P)	Allows access to its LUNs (logical units; real disks or virtual disks created using hardware) via the primary (active) path on a single controller (also known as an access port or a storage processor) during normal operation.
	In implicit failover mode (or autotrespass mode), an A/P array automatically fails over by scheduling I/O to the secondary (passive) path on a separate controller if the primary path fails. This passive port is not used for I/O until the active port fails. In A/P arrays, path failover can occur for a single LUN if I/O fails on the primary path.
	This array mode supports concurrent I/O and load balancing by having multiple primary paths into a controller. This functionality is provided by a controller with multiple ports, or by the insertion of a SAN switch between an array and a controller. Failover to the secondary (passive) path occurs only if all the active primary paths fail.
Active/Passive in explicit failover mode or non-autotrespass mode (A/PF)	The appropriate command must be issued to the array to make the LUNs fail over to the secondary path.
	This array mode supports concurrent I/O and load balancing by having multiple primary paths into a controller. This functionality is provided by a controller with multiple ports, or by the insertion of a SAN switch between an array and a controller. Failover to the secondary (passive) path occurs only if all the active primary paths fail.

Table 1-1(continued)

Array type	Description
Active/Passive with LUN group failover (A/PG)	For Active/Passive arrays with LUN group failover (A/PG arrays), a group of LUNs that are connected through a controller is treated as a single failover entity. Unlike A/P arrays, failover occurs at the controller level, and not for individual LUNs. The primary controller and the secondary controller are each connected to a separate group of LUNs. If a single LUN in the primary controller's LUN group fails, all LUNs in that group fail over to the secondary controller.
	This array mode supports concurrent I/O and load balancing by having multiple primary paths into a controller. This functionality is provided by a controller with multiple ports, or by the insertion of a SAN switch between an array and a controller. Failover to the secondary (passive) path occurs only if all the active primary paths fail.

Table 1-1(continued)

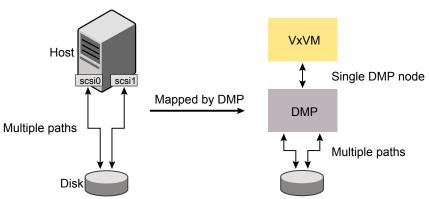

An array policy module (APM) may define array types to DMP in addition to the standard types for the arrays that it supports.

Dynamic Multi-Pathing uses DMP metanodes (DMP nodes) to access disk devices connected to the system. For each disk in a supported array, DMP maps one node to the set of paths that are connected to the disk. Additionally, DMP associates the appropriate multi-pathing policy for the disk array with the node.

For disks in an unsupported array, DMP maps a separate node to each path that is connected to a disk. The raw and block devices for the nodes are created in the directories /dev/vx/rdmp and /dev/vx/dmp respectively.

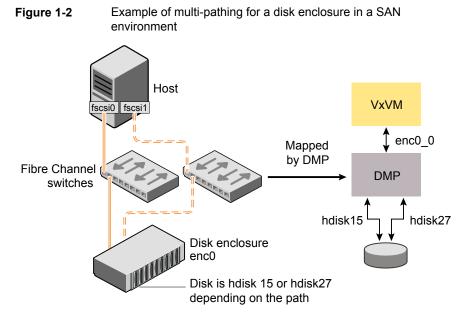

Figure 1-1 shows how DMP sets up a node for a disk in a supported disk array.

DMP implements a disk device naming scheme that allows you to recognize to which array a disk belongs.

Figure 1-2 shows an example where two paths, hdisk15 and hdisk27, exist to a single disk in the enclosure, but VxVM uses the single DMP node, enc0_0, to access it.

See "About enclosure-based naming" on page 24.

How DMP monitors I/O on paths

In VxVM prior to release 5.0, DMP had one kernel daemon (errord) that performed error processing, and another (restored) that performed path restoration activities.

From release 5.0, DMP maintains a pool of kernel threads that are used to perform such tasks as error processing, path restoration, statistics collection, and SCSI request callbacks. The name restored has been retained for backward compatibility.

One kernel thread responds to I/O failures on a path by initiating a probe of the host bus adapter (HBA) that corresponds to the path. Another thread then takes the appropriate action according to the response from the HBA. The action taken can be to retry the I/O request on the path, or to fail the path and reschedule the I/O on an alternate path.

The restore kernel task is woken periodically (by default, every 5 minutes) to check the health of the paths, and to resume I/O on paths that have been restored. As some paths may suffer from intermittent failure, I/O is only resumed on a path if the path has remained healthy for a given period of time (by default, 5 minutes). DMP can be configured with different policies for checking the paths.

See "Configuring DMP path restoration policies" on page 145.

The statistics-gathering task records the start and end time of each I/O request, and the number of I/O failures and retries on each path. DMP can be configured to use this information to prevent the SCSI driver being flooded by I/O requests. This feature is known as I/O throttling.

If an I/O request relates to a mirrored volume, VxVM specifies the FAILFAST flag. In such cases, DMP does not retry failed I/O requests on the path, and instead marks the disks on that path as having failed.

See "Path failover mechanism" on page 17.

See "I/O throttling" on page 18.

Path failover mechanism

DMP enhances system availability when used with disk arrays having multiple paths. In the event of the loss of a path to a disk array, DMP automatically selects the next available path for I/O requests without intervention from the administrator.

DMP is also informed when a connection is repaired or restored, and when you add or remove devices after the system has been fully booted (provided that the operating system recognizes the devices correctly).

If required, the response of DMP to I/O failure on a path can be tuned for the paths to individual arrays. DMP can be configured to time out an I/O request either after

a given period of time has elapsed without the request succeeding, or after a given number of retries on a path have failed.

See "Configuring the response to I/O failures" on page 140.

Subpaths Failover Group (SFG)

A subpaths failover group (SFG) represents a group of paths which could fail and restore together. When an I/O error is encountered on a path in an SFG, DMP does proactive path probing on the other paths of that SFG as well. This behavior adds greatly to the performance of path failover thus improving I/O performance. Currently the criteria followed by DMP to form the subpaths failover groups is to bundle the paths with the same endpoints from the host to the array into one logical storage failover group.

See "Configuring Subpaths Failover Groups (SFG)" on page 143.

Low Impact Path Probing (LIPP)

The restore daemon in DMP keeps probing the LUN paths periodically. This behavior helps DMP to keep the path states up-to-date even when no I/O occurs on a path. Low Impact Path Probing adds logic to the restore daemon to optimize the number of the probes performed while the path status is being updated by the restore daemon. This optimization is achieved with the help of the logical subpaths failover groups. With LIPP logic in place, DMP probes only a limited number of paths within a subpaths failover group (SFG), instead of probing all the paths in an SFG. Based on these probe results, DMP determines the states of all the paths in that SFG.

See "Configuring Low Impact Path Probing (LIPP)" on page 143.

I/O throttling

If I/O throttling is enabled, and the number of outstanding I/O requests builds up on a path that has become less responsive, DMP can be configured to prevent new I/O requests being sent on the path either when the number of outstanding I/O requests has reached a given value, or a given time has elapsed since the last successful I/O request on the path. While throttling is applied to a path, the new I/O requests on that path are scheduled on other available paths. The throttling is removed from the path if the HBA reports no error on the path, or if an outstanding I/O request on the path succeeds.

See "Configuring the I/O throttling mechanism" on page 142.

Load balancing

By default, DMP uses the Minimum Queue I/O policy for load balancing across paths for all array types. Load balancing maximizes I/O throughput by using the total bandwidth of all available paths. I/O is sent down the path that has the minimum outstanding I/Os.

For Active/Passive (A/P) disk arrays, I/O is sent down the primary paths. If all of the primary paths fail, I/O is switched over to the available secondary paths. As the continuous transfer of ownership of LUNs from one controller to another results in severe I/O slowdown, load balancing across primary and secondary paths is not performed for A/P disk arrays unless they support concurrent I/O.

For other arrays, load balancing is performed across all the currently active paths.

You can change the I/O policy for the paths to an enclosure or disk array. This operation is an online operation that does not impact the server or require any downtime.

See "Specifying the I/O policy" on page 131.

Using DMP with LVM boot disks

The Logical Volume Manager (LVM) in AIX is incapable of switching between multiple paths that may exist to the boot disk. If the path that LVM selects becomes unavailable at boot time, the root file system is disabled, and the boot fails. DMP can be configured to overcome this problem by ensuring that an alternate path is available at boot time.

Support for LVM bootability over DMP is enabled by running the following command:

/usr/sbin/vxdmpadm native enable vgname=rootvg

Individual DMP nodes or subpaths can be added or removed from the rootvg. The following command needs to be executed after adding or removing the DMP node or subpaths:

/usr/sbin/vxdmpadm native enable vgname=rootvg

Support for LVM bootability over DMP is disabled by running the following command:

/usr/sbin/vxdmpadm native disable vgname=rootvg

LVM bootability over DMP can be verified as being enabled on a system using the following command:

/usr/sbin/vxdmpadm native list vgname=rootvg

See the vxdmpadm(1M) manual page.

Disabling MPIO

The Multiple Path I/O (MPIO) feature was introduced in AIX 5.2 to manage disks and LUNs with multiple paths. By default, MPIO is enabled on all disks and LUNs that have this capability, which prevents DMP or other third-party multi-pathing drivers (such as EMC PowerPath) from managing the paths to such devices.

To allow DMP or a third-party multi-pathing driver to manage multi-pathing instead of MPIO, you must install suitable Object Data Manager (ODM) definitions for the devices on the host. Without these ODM definitions, MPIO consolidates the paths, and DMP can only see a single path to a given device.

There are several reasons why you might want to configure DMP to manage multi-pathing instead of MPIO:

- Using DMP can enhance array performance if an ODM defines properties such as queue depth, queue type, and timeout for the devices.
- The I/O fencing features of the Storage Foundation HA or Storage Foundation Real Application Cluster software do not work with MPIO devices.
- The Device Discover Layer (DDL) component of DMP provides value-added services including extended attributes like RAID levels, thin provisioning attributes, hardware mirrors, snapshots, transport type, SFGs, array port IDs. These services are not available for MPIO-controlled devices.

Use the following procedure to configure DMP in place of MPIO.

To disable MPIO

1 Obtain the required ODM definitions.

Contact the array vendor to obtain ODM definitions for the array type and the version of AIX on your system. The ODM definition should permit either DMP or the array vendor's multi-pathing driver to discover the devices in the supported array.

Some array vendors do not distribute ODM pre-definitions for their arrays for AIX. In this case, you can use the devices as hdisk devices, as long as MPIO does not claim these LUNs.

- 2 Unmount any file systems and stop all applications such as databases that are configured on VxVM volumes.
- **3** Stop all I/O to the VxVM volumes by entering the following command for each disk group:

```
# vxvol -g diskgroup stopall
```

4 Use the vxprint command to verify that no volumes remain open:

vxprint -Aht -e v_open

5 Deport each disk group in turn:

```
# vxdg deport diskgroup
```

6 Use the following command to remove each hdisk device that MPIO has configured to the arrays:

```
# rmdev -dl hdisk_device
```

Alternatively, use the smitty rmdev command.

7 Use the installp command to install the replacement ODM filesets:

```
# installp -agXd ODM_fileset ...
```

Alternately, you can use the smitty installp command.

- 8 Reboot the system so that the new ODM definitions are used to perform device discovery.
- **9** Use the vxdmpadm command to check that DMP now has access to all the paths to the devices. The following command displays a list of HBA controllers that are configured on a system:

vxdmpadm listctlr all

The next command displays information about all the paths that are connected to a particular HBA controller:

vxdmpadm getsubpaths ctlr=controller_name

For example to display the paths that are connected to the fscsi2 controller:

```
# vxdmpadm getsubpaths ctlr=fscsi2
```

DMP in a clustered environment

In a clustered environment where Active/Passive (A/P) type disk arrays are shared by multiple hosts, all nodes in the cluster must access the disk through the same physical storage controller port. Accessing a disk through multiple paths simultaneously can severely degrade I/O performance (sometimes referred to as the ping-pong effect). Path failover on a single cluster node is also coordinated across the cluster so that all the nodes continue to share the same physical path. Prior to release 4.1 of VxVM, the clustering and DMP features could not handle automatic failback in A/P arrays when a path was restored, and did not support failback for explicit failover mode arrays. Failback could only be implemented manually by running the vxdctl enable command on each cluster node after the path failure had been corrected. From release 4.1, failback is now an automatic cluster-wide operation that is coordinated by the master node. Automatic failback in explicit failover mode arrays is also handled by issuing the appropriate low-level command.

Note: Support for automatic failback of an A/P array requires that an appropriate Array Support Library (ASL) is installed on the system. An Array Policy Module (APM) may also be required.

See "About discovering disks and dynamically adding disk arrays" on page 151.

For Active/Active type disk arrays, any disk can be simultaneously accessed through all available physical paths to it. In a clustered environment, the nodes do not need to access a disk through the same physical path.

See "How to administer the Device Discovery Layer" on page 155.

See "Configuring Array Policy Modules" on page 147.

About enabling or disabling controllers with shared disk groups

Prior to release 5.0, Veritas Volume Manager (VxVM) did not allow enabling or disabling of paths or controllers connected to a disk that is part of a shared Veritas Volume Manager disk group. From VxVM 5.0 onward, such operations are supported on shared DMP nodes in a cluster.

Multiple paths to disk arrays

Some disk arrays provide multiple ports to access their disk devices. These ports, coupled with the host bus adaptor (HBA) controller and any data bus or I/O processor local to the array, make up multiple hardware paths to access the disk devices. Such disk arrays are called multipathed disk arrays. This type of disk array can be connected to host systems in many different configurations, (such as multiple ports connected to different controllers on a single host, chaining of the ports through a single controller on a host, or ports connected to different hosts simultaneously).

See "How DMP works" on page 13.

Device discovery

Device discovery is the term used to describe the process of discovering the disks that are attached to a host. This feature is important for DMP because it needs to support a growing number of disk arrays from a number of vendors. In conjunction with the ability to discover the devices attached to a host, the Device Discovery service enables you to add support for new disk arrays. The Device Discovery uses a facility called the Device Discovery Layer (DDL).

The DDL enables you to add support for new disk arrays without the need for a reboot.

This means that you can dynamically add a new disk array to a host, and run a command which scans the operating system's device tree for all the attached disk devices, and reconfigures DMP with the new device database.

See "How to administer the Device Discovery Layer" on page 155.

Disk devices

The device name (sometimes referred to as devname or disk access name) defines the name of a disk device as it is known to the operating system.

Such devices are usually, but not always, located in the /dev directory. Devices that are specific to hardware from certain vendors may use their own path name conventions.

Dynamic Multi-Pathing (DMP) uses the device name to create metadevices in the /dev/vx/[r]dmp directories. DMP uses the metadevices (or DMP nodes) to represent disks that can be accessed by one or more physical paths, perhaps via different controllers. The number of access paths that are available depends on whether the disk is a single disk, or is part of a multiported disk array that is connected to a system.

You can use the vxdisk utility to display the paths that are subsumed by a DMP metadevice, and to display the status of each path (for example, whether it is enabled or disabled).

See "How DMP works" on page 13.

Device names may also be remapped as enclosure-based names.

See "Disk device naming in DMP" on page 24.

Disk device naming in DMP

Device names for disks are assigned according to the naming scheme which you specify to DMP. The format of the device name may vary for different categories of disks.

See "Disk categories" on page 152.

Device names can use one of the following naming schemes:

- operating system-based naming.
 See "About operating system-based naming" on page 24.
- enclosure-based naming.
 See "About enclosure-based naming" on page 24.

Devices with device names longer than 31 characters always use enclosure-based names.

By default, DMP uses enclosure-based naming. You can change the disk device naming scheme if required.

See "Changing the disk device naming scheme" on page 166.

About operating system-based naming

In the OS-based naming scheme, all disk devices are named using the hdisk# format, where # is a series number.

DMP assigns the name of the DMP meta-device (disk access name) from the multiple paths to the disk. DMP sorts the names by hdisk number, and selects the smallest number. For example, hdisk1 rather than hdisk2. This behavior make it easier to correlate devices with the underlying storage.

If a CVM cluster is symmetric, each node in the cluster accesses the same set of disks. This naming scheme makes the naming consistent across nodes in a symmetric cluster.

By default, OS-based names are not persistent, and are regenerated if the system configuration changes the device name as recognized by the operating system. If you do not want the OS-based names to change after reboot, set the persistence attribute for the naming scheme.

See "Changing the disk device naming scheme" on page 166.

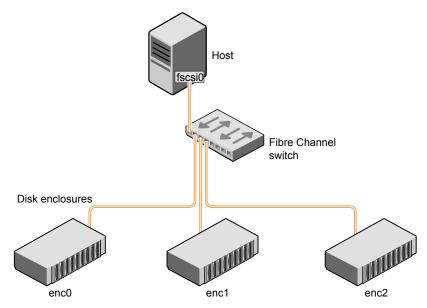

About enclosure-based naming

In a Storage Area Network (SAN) that uses Fibre Channel switches, information about disk location provided by the operating system may not correctly indicate the

physical location of the disks. Enclosure-based naming allows DMP to access enclosures as separate physical entities. By configuring redundant copies of your data on separate enclosures, you can safeguard against failure of one or more enclosures.

Figure 1-3 shows a typical SAN environment where host controllers are connected to multiple enclosures through a Fibre Channel switch.

Figure 1-3 Example configuration for disk enclosures connected through a Fibre Channel switch

In such a configuration, enclosure-based naming can be used to refer to each disk within an enclosure. For example, the device names for the disks in enclosure enc0 are named enc0_0, enc0_1, and so on. The main benefit of this scheme is that it lets you quickly determine where a disk is physically located in a large SAN configuration.

In most disk arrays, you can use hardware-based storage management to represent several physical disks as one LUN to the operating system. In such cases, VxVM also sees a single logical disk device rather than its component disks. For this reason, when reference is made to a disk within an enclosure, this disk may be either a physical disk or a LUN.

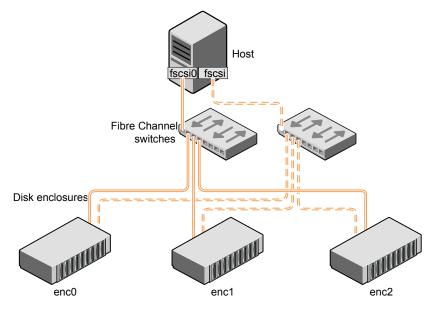

Another important benefit of enclosure-based naming is that it enables VxVM to avoid placing redundant copies of data in the same enclosure. This is a good thing to avoid as each enclosure can be considered to be a separate fault domain. For

example, if a mirrored volume were configured only on the disks in enclosure encl, the failure of the cable between the switch and the enclosure would make the entire volume unavailable.

If required, you can replace the default name that DMP assigns to an enclosure with one that is more meaningful to your configuration.

Figure 1-4 shows a High Availability (HA) configuration where redundant-loop access to storage is implemented by connecting independent controllers on the host to separate switches with independent paths to the enclosures.

Such a configuration protects against the failure of one of the host controllers (fscsi0 and fscsi1), or of the cable between the host and one of the switches. In this example, each disk is known by the same name to VxVM for all of the paths over which it can be accessed. For example, the disk device enc0_0 represents a single disk for which two different paths are known to the operating system, such as hdisk15 and hdisk27.

See "Disk device naming in DMP" on page 24.

See "Changing the disk device naming scheme" on page 166.

To take account of fault domains when configuring data redundancy, you can control how mirrored volumes are laid out across enclosures.

Summary of enclosure-based naming

By default, DMP uses enclosure-based naming.

Enclosure-based naming operates as follows:

- All fabric or non-fabric disks in supported disk arrays are named using the enclosure_name_# format. For example, disks in the supported disk array, enggdept are named enggdept_0, enggdept_1, enggdept_2 and so on. You can use the vxdmpadm command to administer enclosure names. See the vxdmpadm(1M) manual page.
- Disks in the DISKS category (JBOD disks) are named using the Disk # format.
- Devices in the OTHER_DISKS category are disks that are not multipathed by DMP.
 Devices in this category have names of the form hdisk#, which are the same as the device names generated by AIX.

By default, enclosure-based names are persistent, so they do not change after a reboot.

If a CVM cluster is symmetric, each node in the cluster accesses the same set of disks. Enclosure-based names provide a consistent naming system so that the device names are the same on each node.

To display the native OS device names of a DMP disk (such as mydg01), use the following command:

vxdisk path | grep diskname

See "Renaming an enclosure" on page 140.

See "Disk categories" on page 152.

See "Enclosure based naming with the Array Volume Identifier (AVID) attribute" on page 27.

Enclosure based naming with the Array Volume Identifier (AVID) attribute

By default, Dynamic Multi-Pathing (DMP) assigns enclosure-based names to DMP metadevices using an array-specific attribute called the Array Volume ID (AVID). The AVID provides a unique identifier for the LUN that is provided by the array. The ASL corresponding to the array provides the AVID property. Within an array enclosure, DMP uses the Array Volume Identifier (AVID) as an index in the DMP metanode name. The DMP metanode name is in the format enclosureID AVID.

With the introduction of AVID to the enclosure-based naming (EBN) naming scheme, identifying storage devices becomes much easier. The array volume identifier (AVID) enables you to have consistent device naming across multiple nodes connected to

the same storage. The disk access name never changes, because it is based on the name defined by the array itself.

Note: DMP does not support AVID with PowerPath names.

If DMP does not have access to a device's AVID, it retrieves another unique LUN identifier called the LUN serial number. DMP sorts the devices based on the LUN Serial Number (LSN), and then assigns the index number. All hosts see the same set of devices, so all hosts will have the same sorted list, leading to consistent device indices across the cluster. In this case, the DMP metanode name is in the format *enclosureID index*.

DMP also supports a scalable framework, that allows you to fully customize the device names on a host by applying a device naming file that associates custom names with cabinet and LUN serial numbers.

If a CLuster Volume Manager (CVM) cluster is symmetric, each node in the cluster accesses the same set of disks. Enclosure-based names provide a consistent naming system so that the device names are the same on each node.

The Dynamic Multi-Pathing (DMP) utilities such as vxdisk list display the DMP metanode name, which includes the AVID property. Use the AVID to correlate the DMP metanode name to the LUN displayed in the array management interface (GUI or CLI).

For example, on an EMC CX array where the enclosure is emc_clariion0 and the array volume ID provided by the ASL is 91, the DMP metanode name is emc_clariion0_91. The following sample output shows the DMP metanode names:

\$ vxdisk list

emc_clariion0_91	auto:cdsdisk	emc_clariion0_91	dg1	online shared
emc_clariion0_92	auto:cdsdisk	emc_clariion0_92	dg1	online shared
emc_clariion0_93	auto:cdsdisk	emc_clariion0_93	dg1	online shared
emc_clariion0_282	auto:cdsdisk	emc_clariion0_282	dg1	online shared
emc_clariion0_283	auto:cdsdisk	emc_clariion0_283	dg1	online shared
emc_clariion0_284	auto:cdsdisk	emc_clariion0_284	dg1	online shared

Chapter

Setting up DMP to manage native devices

This chapter includes the following topics:

- About setting up DMP to manage native devices
- Displaying the native multi-pathing configuration
- Migrating LVM volume groups to DMP
- Migrating to DMP from EMC PowerPath
- Migrating to DMP from Hitachi Data Link Manager (HDLM)
- Migrating to DMP from IBM Multipath IO (MPIO) or MPIO path control module (PCM)
- Using Dynamic Multi-Pathing (DMP) devices with Oracle Automatic Storage Management (ASM)
- Adding DMP devices to an existing LVM volume group or creating a new LVM volume group
- Removing DMP support for native devices

About setting up DMP to manage native devices

You can use DMP instead of third-party drivers for advanced storage management. This section describes how to set up DMP to manage native LVM devices and any logical volume that operates on those devices.

After you install DMP, set up DMP for use with LVM. To set up DMP for use with LVM, turn on the dmp_native_support tunable. When this tunable is turned on, DMP enables support for LVM on any device that does not have a VxVM label and is not

in control of any third party multi-pathing (TPD) software. In addition, turning on the dmp_native_support tunable migrates any LVM volume groups that are not in use onto DMP devices.

The dmp_native_support tunable enables DMP support for LVM, as follows:

LVM volume groups	If the LVM volume groups are not in use, turning on native support migrates the volume groups to DMP devices.
	If the LVM volume groups are in use, then perform the steps to turn off the volume groups and migrate the volume groups to DMP.
Veritas Volume Manager (VxVM) devices	Native support is not enabled for any device that has a VxVM label. To make the device available for LVM, remove the VxVM label.
	VxVM devices can coexist with native devices under DMP control.
Devices that are multi-pathed with Third-party drivers (TPD)	If a disk is already multi-pathed with a third-party driver (TPD), DMP does not manage the devices unless you remove TPD support. After removing TPD support, turn on the dmp_native_support tunable to migrate the devices.
	If LVM volume groups are constructed over TPD devices, then perform the steps to migrate the LVM volume groups onto DMP devices.
	See "Migrating LVM volume groups to DMP" on page 31.

To turn on the dmp_native_support tunable, use the following command:

```
# vxdmpadm settune dmp_native_support=on
```

The first time this operation is performed, the command reports if a volume group is in use, and does not migrate that volume group. To migrate the volume group onto DMP, stop the volume group. Then execute the vxdmpadm settune command again to migrate the volume group onto DMP.

To verify the value of the dmp_native_support tunable, use the following command:

<pre># vxdmpadm gettune dmp_native_support</pre>					
Tunable	Current Value	Default Value			
dmp_native_support	on	off			

Displaying the native multi-pathing configuration

When DMP is enabled for native devices, the dmp_native_support tunable is set to ON. When the tunable is ON, all DMP disks are available for native volumes except:

Devices that have a VxVM label
 If you initialize a disk for VxVM use, then the native multi-pathing feature is automatically disabled for the disk.

You can use the disks for native multi-pathing if you remove them from VxVM use.

 Devices that are multi-pathed with Third-party drivers
 If a disk is already multi-pathed with a third-party driver (TPD), DMP does not manage the devices unless TPD support is removed.

To display whether DMP is enabled

1 Display the attribute dmp_native_support.

```
# vxdmpadm gettune dmp_native_support
```

Tunable	Current Value	Default Value
dmp_native_support	on	off

2 When the dmp_native_support tunable is ON, use the vxdisk list command to display available disks. Disks available to LVM display with the TYPE auto:none. Disks that are already in use by LVM display with the TYPE auto:LVM.

Migrating LVM volume groups to DMP

You can use DMP instead of third-party drivers for advanced storage management. This section describes how to set up DMP to manage LVM volume groups and the file systems operating on them.

To set up DMP, migrate the devices from the existing third-party device drivers to DMP.

Table 2-1 shows the supported native solutions and migration paths.

Operating system	Native solution	Migration procedure
AIX	EMC PowerPath	See "Migrating to DMP from EMC PowerPath" on page 32.
AIX	Hitachi Data Link Manager (HDLM)	See "Migrating to DMP from Hitachi Data Link Manager (HDLM)" on page 33.
AIX	IBM Multipath IO (MPIO)	See "Migrating to DMP from IBM Multipath IO (MPIO) or MPIO path control module (PCM)" on page 34.

 Table 2-1
 Supported migration paths

Migrating to DMP from EMC PowerPath

This procedure describes removing devices from EMC PowerPath control and enabling DMP on the devices.

Make sure that all paths belonging to the migrating PowerPath devices are in healthy state during the migration.

Plan for application downtime for the following procedure.

To remove devices from EMC PowerPath control and enable DMP

1 Stop the applications that use the PowerPath meta-devices.

In a VCS environment, stop the VCS service group of the application, which will stop the application.

- 2 Unmount any file systems that use the volume group on the PowerPath device.
- 3 Stop the LVM volume groups that use the PowerPath device.

varyoffvg vgroupname

4 If the root volume group (rootvg) is under PowerPath control, migrate the rootvg to DMP.

See "Migrating a SAN root disk from EMC PowerPath to DMP control" on page 84.

5 Remove the disk access names for the PowerPath devices from VxVM.

vxdisk rm emcpowerXXXX

Where *emcpowerXXXX* is the name of the EMC PowerPath device.

6 Take the device out of PowerPath control:

```
# powermt unmanage dev=pp_device_name
or
# powermt unmanage class=array class
```

7 Verify that the PowerPath device has been removed from PowerPath control.

```
# powermt display dev=all
```

8 Run a device scan to bring the devices under DMP control:

```
# vxdisk scandisks
```

9 Turn on the DMP support for the LVM volume group.

vxdmpadm settune dmp_native_support=on

The above command also enables DMP support for LVM root.

- **10** Mount the file systems.
- **11** Restart the applications.

Migrating to DMP from Hitachi Data Link Manager (HDLM)

This procedure describes removing devices from HDLM control and enabling DMP on the devices.

Note: DMP cannot co-exist with HDLM; HDLM must be removed from the system.

Plan for application and system downtime for the following procedure.

To remove devices from Hitachi Data Link Manager (HDLM) and enable DMP

- 1 Stop the applications using the HDLM meta-device
- 2 Unmount any file systems that use the volume group on the HDLM device.

In a VCS environment, stop the VCS service group of the application, which will stop the application.

- **3** Stop the LVM volume groups that use the HDLM device.
 - # varyoffvg vgroupname

- 4 Uninstall the HDLM package.
- **5** Turn on the DMP support for the LVM volume group.

vxdmpadm settune dmp_native_support=on

The above command also enables DMP support for LVM root.

- 6 Reboot the system.
- 7 After the reboot, DMP controls the devices. If there were any LVM volume groups on HDLM devices they are migrated onto DMP devices.
- 8 Mount the file systems.
- **9** Restart the applications.

Migrating to DMP from IBM Multipath IO (MPIO) or MPIO path control module (PCM)

This procedure describes how to migrate to DMP from IBM Multipath IO (MPIO) or an MPIO path control module (PCM). The procedure includes removing the devices from MPIO control and enabling DMP on the devices.

If an MPIO PCM is installed, you need to remove the PCM before you install the ODM packages from the vendor.

Plan for system downtime for the following procedure.

The migration steps involve system downtime on a host due to the following:

- Need to stop applications
- Need to stop the VCS services if using VCS
- The procedure involves one or more host reboots

To take the devices out of MPIO control and enable DMP

1 Obtain the corresponding MPIO-suppression Object Data Manager (ODM) fileset for the array from the array vendor.

If the MPIO suppression ODM fileset is not available, use the $\tt vxmpio$ utility to remove the device from MPIO.

- 2 Stop the applications that use the MPIO devices.
- **3** Unmount the file systems on the MPIO devices.
- 4 Vary off the LVM volume groups.

```
# varyoffvg vgroupname
```

- 5 If an MPIO PCM is present, remove all VxVM devices that the PCM controls.
 - # vxdisk rm dmpnodename
- 6 If the MPIO PCM does not control the rootvg devices, then uninstall the PCM.

If a PCM controls the rootvg devices, then you must obtain the script from the PCM vendor to uninstall the PCM. For example, if the Subsystem Device Driver Path Control Module (SDDPCM) controls the devices, then contact IBM to obtain the script to remove SDDPCM.

7 Install the MPIO-suppression ODM fileset that you obtained from the array vendor in step 1. Refer to the array vendor documentation for the installation procedure.

Some array vendors do not distribute ODM Pre-defines for their arrays for AIX. In this case, you can use the devices as hdisk devices, as long as MPIO does not claim these LUNs.

8 Turn on the DMP support for the LVM volume groups.

vxdmpadm settune dmp_native_support=on

The above command also enables DMP support for LVM root.

- 9 Reboot the system.
- **10** After the reboot, DMP controls the devices. Any LVM volume groups on MPIO devices are migrated onto DMP devices.
- **11** Mount the file systems.
- **12** Restart the applications.

Using Dynamic Multi-Pathing (DMP) devices with Oracle Automatic Storage Management (ASM)

This release of DMP supports using DMP devices with Oracle Automatic Storage Management (ASM). DMP supports the following operations:

- See "Enabling Dynamic Multi-Pathing (DMP) devices for use with Oracle Automatic Storage Management (ASM)" on page 36.
- See "Removing Dynamic Multi-Pathing (DMP) devices from the listing of Oracle Automatic Storage Management (ASM) disks" on page 37.
- See "Migrating Oracle Automatic Storage Management (ASM) disk groups on operating system devices to Dynamic Multi-Pathing (DMP) devices" on page 37.

Enabling Dynamic Multi-Pathing (DMP) devices for use with Oracle Automatic Storage Management (ASM)

Enable DMP support for Oracle Automatic Storage Management (ASM) to make DMP devices visible to ASM as available disks. DMP support for ASM is available for char devices (/dev/vx/rdmp/*).

To make DMP devices visible to ASM

1 From ASM, make sure ASM_DISKSTRING is set to the correct value:

/dev/vx/rdmp/*

For example:

2 As root user, enable DMP devices for use with ASM.

```
# vxdmpraw enable username groupname mode [devicename ...]
```

where *username* represents the ASM user running the ASM instance, groupname represents the UNIX/Linux groupname of the specified user-id, and mode represents the permissions to set on the device. If you specify one or more *devicenames*, DMP support for ASM is enabled for those devices. If you do not specify a *devicename*, DMP support is enabled for all devices in the system that have an ASM signature.

For example:

```
# vxdmpraw enable oracle dba 765 eva4k6k0_1
```

ASM support is enabled. The access permissions for the DMP device are set to the permissions specified by *mode*. The changes are persistent across reboots.

3 From ASM, confirm that ASM can see these new devices.

- 4 From ASM, increase the Oracle heartbeat wait time from the default value of 15 seconds. To prevent the Oracle application from marking the disk as offline during the DMP failover, increase the default value for asm hbeatiowait.
 - For example, to set the value to 360 seconds:

```
SQL> alter system set "_asm_hbeatiowait"=360 scope=spfile sid='*';
```

Restart the ASM instance for the new parameter to take effect.

Removing Dynamic Multi-Pathing (DMP) devices from the listing of Oracle Automatic Storage Management (ASM) disks

To remove DMP devices from the listing of ASM disks, disable DMP support for ASM from the device. You cannot remove DMP support for ASM from a device that is in an ASM disk group.

To remove the DMP device from the listing of ASM disks

- 1 If the device is part of any ASM disk group, remove the device from the ASM disk group.
- 2 As root user, disable DMP devices for use with ASM.
 - # vxdmpraw disable diskname

For example:

vxdmpraw disable eva4k6k0_1

Migrating Oracle Automatic Storage Management (ASM) disk groups on operating system devices to Dynamic Multi-Pathing (DMP) devices

When an existing ASM disk group uses operating system native devices as disks, you can migrate these devices to Dynamic Multi-Pathing control. If the OS devices

are controlled by other multi-pathing drivers, this operation requires system downtime to migrate the devices to DMP control.

Plan for system downtime for the following procedure.

After this procedure, the ASM disk group uses the migrated DMP devices as its disks.

"From ASM" indicates that you perform the step as the user running the ASM instance.

"As root user" indicates that you perform the step as the root user.

To migrate an ASM disk group from operating system devices to DMP devices

- **1** Stop the applications and shut down the database.
- **2** From ASM, identify the ASM disk group that you want to migrate, and identify the disks under its control.
- **3** From ASM, dismount the ASM disk group.
- 4 If the devices are controlled by other multi-pathing drivers, migrate the devices to DMP control. Perform these steps as root user.

Migrate from MPIO or PowerPath.

See "About setting up DMP to manage native devices" on page 29.

5 As root user, enable DMP support for the ASM disk group identified in step 2.

vxdmpraw enable username groupname mode [devicename ...]

where *username* represents the ASM user running the ASM instance, groupname represents the UNIX/Linux groupname of the specified user-id, and mode represents the permissions to set on the device. If you specify one or more *devicenames*, DMP support for ASM is enabled for those devices. If you do not specify a *devicename*, DMP support is enabled for all devices in the system that have an ASM signature.

- **6** From ASM, set ASM_DISKSTRING as appropriate. The preferred setting is /dev/vx/rdmp/*
- 7 From ASM, confirm that the devices are available to ASM.
- 8 From ASM, mount the ASM disk groups. The disk groups are mounted on DMP devices.

Example: To migrate an ASM disk group from operating system devices to DMP devices

1 From ASM, identify the ASM disk group that you want to migrate, and identify the disks under its control.

SQL> select name, state from v\$asm_diskgroup; NAME STATE ASM_DG1 MOUNTED SQL> select name,path,header_status from v\$asm_disk; NAME PATH HEADER_STATUS ASM_DG1_0000 /dev/rhdisk43 MEMBER ASM_DG1_0001 /dev/rhdisk51 MEMBER ASM_DG1_0002 /dev/rhdisk97 MEMBER

2 From ASM, dismount the ASM disk group.

SQL> alter diskgroup ASM_DG1 dismount; Diskgroup altered.

3 If the devices are controlled by other multi-pathing drivers, migrate the devices to DMP control. Perform these steps as root user.

See "About setting up DMP to manage native devices" on page 29.

- **4** As root user, enable DMP support for the ASM disk group identified in step 2, in one of the following ways:
 - To migrate selected ASM diskgroups, use the vxdmpadm command to determine the DMP nodes that correspond to the OS devices.

vxdmpadm getdmpnode nodename=hdisk4
NAME STATE ENCLR-TYPE PATHS ENBL DSBL ENCLR-NAME
EVA4K6K0_0 ENABLED EVA4K6K 4 4 0 EVA4K6K0

Use the device name in the command below:

```
# vxdmpraw enable oracle dba 660 eva4k6k0_0 \
    eva4k6k0_9 emc_clariion0_243
```

 If you do not specify a *devicename*, DMP support is enabled for all devices in the disk group that have an ASM signature. For example:

vxdmpraw enable oracle dba 660

5 From ASM, set ASM_DISKSTRING.

6 From ASM, confirm that the devices are available to ASM.

```
SQL> select path , header_status from v$asm_disk where header status='MEMBER';
```

NAME PATH HEADER_STATUS //dev/vx/rdmp/emc_clariion0_243 MEMBER //dev/vx/rdmp/eva4k6k0_9 MEMBER //dev/vx/rdmp/eva4k6k0_1 MEMBER

7 From ASM, mount the ASM disk groups. The disk groups are mounted on DMP devices.

```
SQL> alter diskgroup ASM DG1 mount;
Diskgroup altered.
SQL> select name, state from v$asm diskgroup;
NAME
                        STATE
_____
ASM DG1
                        MOUNTED
SQL> select name, path, header status from v$asm disk where
header status='MEMBER';
NAME
          PATH
                                   HEADER STATUS
_____
ASM DG1 0002 /dev/vx/rdmp/emc clariion0 243 MEMBER
ASM DG1 0000 /dev/vx/rdmp/eva4k6k0 1
                                  MEMBER
ASM DG1 0001 /dev/vx/rdmp/eva4k6k0 9 MEMBER
```

Adding DMP devices to an existing LVM volume group or creating a new LVM volume group

When the dmp_native_support is ON, you can create a new LVM volume group on an available DMP device. You can also add an available DMP device to an existing LVM volume group. After the LVM volume groups are on DMP devices, you can use any of the LVM commands to manage the volume groups.

To create a new LVM volume group on a DMP device or add a DMP device to an existing LVM volume group

1 Choose disks that are available for use by LVM.

Use the vxdisk list command to identify these types of disks.

Disks that are not in use by VxVM
 The output of vxdisk list shows these disks with the Type auto:none and the Status as online invalid.

The example shows available disks.

vxdisk list

DEVICE	TYPE	DISK	GROUP	STATUS
emc_clariion0_84	auto:none	-	-	online invalid
emc_clariion0_85	auto:none	-	-	online invalid

2 Identify the ODM device name that corresponds to the device. The ODM device name is a truncated form of the DMP device name, since the ODM database requires a shorter name. The dmpname is an attribute of the ODM device name.

In this example, the DMP device name is emc_clariion0_84, and the ODM device name is emc_clari0_84. The enclosure index and the array volume ID (AVID) in the enclosure based name (EBN) are retained from the DMP device name.

```
# lspv | grep emc clari0
emc clari0 84
                none
                                           None
emc clari0 85
                 none
                                           None
# lsdev -Cc disk
. . .
emc clari0 84
               Available
                                 Veritas DMP Device
emc clari0 85
               Available
                                 Veritas DMP Device
# lsattr -El emc clari0 84
dmpname emc clariion0 84 DMP Device name
                                                    True
                         Physical volume identifier True
pvid
         none
unique id DGC%5FRAID%200%5FCK200080300687%5F600601601C101F0
0E5CF099D7209DE11 Unique device identifier True
```

3 Create a new LVM volume group on a DMP device.

Use the ODM device name to specify the DMP device.

```
# mkvg -y newvg emc_clari0_84
0516-1254 mkvg: Changing the PVID in the ODM.
newvg
```

```
# lspv
emc_clari0_84 00c95c90837d5ff8 newvg active
emc_clari0_85 none None
```

4 Add a DMP device to an existing LVM volume group.

Use the ODM device name to specify the DMP device.

```
# extendvg -f newvg emc_clari0_85
0516-1254 mkvg: Changing the PVID in the ODM.
```

```
# lspv
emc_clari0_84 00c95c90837d5ff8 newvg active
emc clari0 85 00c95c90837d612f newvg active
```

5 Run the following command to trigger DMP discovery of the devices:

```
# vxdisk scandisks
```

6 After the discovery completes, the disks are shown as in use by LVM:

```
# vxdisk list
. . .
emc_clariion0_84 auto:LVM - - LVM
emc_clariion0_85 auto:LVM - - LVM
```

Removing DMP support for native devices

The dmp_native_support tunable is persistent across reboots and product upgrades. You can disable native support for an individual device if you initialize it for VxVM, or if you set up TPD multi-pathing for that device.

To remove support for native devices from all DMP devices, turn off the dmp_native_support tunable.

This operation also disables DMP support for LVM rootvg, so it requires that you reboot the system. You can enable DMP support for the LVM rootvg separately, if required.

To turn off the dmp_native support tunable:

vxdmpadm settune dmp native support=off

To view the value of the dmp_native_support tunable:

<pre># vxdmpadm gettune d</pre>	mp_native_support	
Tunable	Current Value	Default Value
dmp_native_support	off	off

To retain DMP support for LVM rootvg after the dmp_native_support tunable is turned off, use the following command:

vxdmpadm native enable vgname=rootvg

Please reboot the system to enable DMP support for LVM bootability

Chapter

Dynamic Multi-Pathing for the Virtual I/O Server

This chapter includes the following topics:

- About Dynamic Multi-Pathing in a Virtual I/O server
- About the Volume Manager (VxVM) component in a Virtual I/O server
- Configuring Dynamic Multi-Pathing (DMP) on Virtual I/O server
- Configuring Dynamic Multi-Pathing (DMP) pseudo devices as virtual SCSI devices
- Extended attributes in VIO client for a virtual SCSI disk

About Dynamic Multi-Pathing in a Virtual I/O server

The Virtual I/O (VIO) server virtualization technology from IBM is a logical partition (LPAR) that runs a trimmed-down version of the AIX operating system. Virtual I/O servers have APV support, which allows sharing of physical I/O resources between virtual I/O clients.

Figure 3-1 illustrates DMP enablement in the Virtual I/O server.

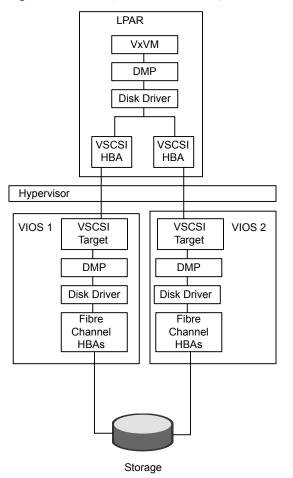

Figure 3-1 Dynamic Multi-Pathing in the Virtual I/O serve

DMP is fully functional in the Virtual I/O server. DMP administration and management commands (vxdmpadm, vxddladm, vxdisk) must be invoked from the non-restricted root shell.

\$ oem_setup_env

Some example commands:

	hdis	k61 ENABLE k80 ENABLE k99 ENABLE	D(A) -	fscsi fscsi fscsi	1 IBM_DS	38x00 il	om_ds8x000 om_ds8x000 om_ds8x000	-
	dmpv	vios1\$ vxdm	npadm liste	enclosure al	.1			
	ENCLR_TYPE	ENCLR_SNO		ARRAY_TYPE	LUN_COUNT	FIRMWAR	E =	
disk ibm ds8x000	Disk TBM DS8v00	DISKS 75ma641	CONNECTED CONNECTED		1	_		

See the PowerVM wiki for more in-depth information about VIO server and virtualization:

http://www.ibm.com/developerworks/wikis/display/virtualization/VIO

For more information, see the PowerVM Virtualization on IBM System p redbook: http://www.redbooks.ibm.com/redpieces/abstracts/sg247940.html

About the Volume Manager (VxVM) component in a Virtual I/O server

Volume Manager (VxVM) is a component of Veritas InfoScale whose functionality is disabled in Virtual I/O server (VIOS). VxVM commands that manage volumes or disk groups are disabled in the VIO server.

In the VIOS, VxVM does not detect disk format information, so the disk status for VxVM disks is shown as unknown. For example:

dmpvios1\$ vxdisk	list			
DEVICE	TYPE	DISK	GROUP	STATUS
disk_0	auto	-	-	unknown
ibm_ds8x000_02c1	auto	-	-	unknown
ibm_ds8x000_0288	auto	-	-	unknown
ibm_ds8x000_029a	auto	-	-	unknown
ibm_ds8x000_0292	auto	-	-	unknown
ibm_ds8x000_0293	auto	-	-	unknown
ibm_ds8x000_0337	auto	-	-	unknown

In the VIOS, VxVM displays an error if you run a command that is disabled, as follows:

dmpvios1\$ vxdisk -f init ibm ds8x000 0288 VxVM vxdisk ERROR V-5-1-5433 Device ibm ds8x000 0288: init failed: Operation not allowed. VxVM is disabled.

```
dmpvios1$ vxdg import datadg
VxVM vxdg ERROR V-5-1-10978 Disk group datadg: import failed:
Operation not allowed. VxVM is disabled.
```

Configuring Dynamic Multi-Pathing (DMP) on Virtual I/O server

You can install DMP in the virtual I/O server (VIOS). This enables the VIO server to export dmpnodes to the VIO clients. The VIO clients access the dmpnodes in the same way as any other vSCSI devices. DMP handles the I/O to the disks backed by the dmpnodes.

For support information concerning running Dynamic Multi-Pathing (DMP) in Virtual I/O server (VIOS), see the *Veritas InfoScale 7.0 Release Notes*.

Dynamic Multi-Pathing (DMP) can operate in the Virtual I/O server. Install DMP on the Virtual I/O server.

To install DMP on the Virtual I/O server

- 1 Log into the VIO server partition.
- 2 Use the oem setup env command to access the non-restricted root shell.
- **3** Install Dynamic Multi-Pathing on the Virtual I/O server.

See the Storage Foundation Configuration and Upgrade Guide.

4 Installing DMP on the VIO server enables the dmp_native_support tunable. Do not set the dmp_native_support tunable to off.

 dmpvios1\$ vxdmpadm gettune dmp_native_support

 Tunable
 Current Value

 ----- -----

 dmp_native_support
 on
 off

Migration options for configuring multi-pathing on a Virtual I/O server:

- Migrate from other multi-pathing solutions to DMP on a Virtual I/O server
- Migrate from MPIO to DMP on a Virtual I/O server for a dual-VIOS configuration
- Migrate from PowerPath to DMP on Virtual I/O server for a dual-VIOS configuration

Virtual I/O Server (VIOS) requirements

To run DMP in VIOS, the minimum VIOS level that is required is 2.2.2.1 or later.

Before installing DMP on VIOS, confirm the following:

If any path to the target disk has SCSI reserve ODM attribute set, then change the attributes to release the SCSI reservation from the paths, on a restart.

If a path has the reserve_policy attribute set, change the reserve_policy attribute to no reserve for all the paths.

```
# lsattr -E1 hdisk557 | grep res
reserve_policy single_path
Reserve Policy True
# chdev -1 hdisk557 -a reserve_policy=no_reserve -P
hdisk557 changed
```

If a path has the reserve_lock attribute set, change the reserve_lockattribute to no.

```
# lsattr -E1 hdisk558 | grep reserve_lock
reserve_lock yes
Reserve Device on open True
# chdev -1 hdisk558 -a reserve_lock=no -P
hdisk558 changed
```

Migrating from other multi-pathing solutions to DMP on Virtual I/O server

DMP supports migrating from AIX MPIO and EMC PowerPath multi-pathing solutions to DMP on Virtual I/O server.

To migrate from other multi-pathing solutions to DMP on a Virtual I/O server

- 1 Before migrating, back up the Virtual I/O servers to use for reverting the system in case of issues.
- 2 Shut down all VIO client partitions that are serviced by the VIOS.
- **3** Log into the VIO server partition. Use the following command to access the non-restricted root shell. All subsequent commands in this procedure must be invoked from the non-restricted shell.

```
$ oem_setup_env
```

- **4** Use commands like <code>lsdev</code> and <code>lsmap</code> to view the configuration.
- 5 Unconfigure all VTD devices from all virtual adapters on the system:

dmpvios1\$ rmdev -p vhost0

Repeat this step for all other virtual adapters.

6 Migrate from the third-party device driver to DMP.

Note that you do not need to do turn on the dmp_native_support again, because it is turned on for VIOS by default. You can use the vxdmpadm gettune dmp_native_support command to verify that the tunable parameter is turned on.

See "Migrating LVM volume groups to DMP" on page 31.

- 7 Reboot the VIO Server partition.
- **8** Use the following command to verify that all Virtual SCSI mappings of TPD multi-pathing solution have been correctly migrated to DMP:

dmpvios1\$ /usr/ios/cli/ioscli lsmap -all

- **9** Repeat step 1 through step 8 for all of the other VIO server partitions of the managed system.
- **10** After all of the VIO Server partitions are successfully migrated to DMP, start all of the VIO client partitions.

Migrating from MPIO to DMP on a Virtual I/O server for a dual-VIOS configuration

This following example procedure illustrates a migration from MPIO to DMP on the Virtual I/O server, in a configuration with two VIO Servers.

Example configuration values:

Managed System: dmpviosp6 VIO server1: dmpvios1 VIO server2: dmpvios2 VIO clients: dmpvioc1 SAN LUNs: IBM DS8K array Current multi-pathing solution on VIO server: IBM MPIO ODM definition fileset required to disable MPIO support for IBM DS8K array LUNs:

devices.fcp.disk.ibm.rte

To migrate dmpviosp6 from MPIO to DMP

1 Before migrating, back up the Virtual I/O server to use for reverting the system in case of issues.

See the IBM website for information about backing up Virtual I/O server.

2 Shut down all of the VIO clients that are serviced by the VIO Server.

dmpvioc1\$ halt

3 Log into the VIO server partition.Use the following command to access the non-restricted root shell. All subsequent commands in this procedure must be invoked from the non-restricted shell.

\$ oem_setup_env

4 The following command shows lsmap output before migrating MPIO VTD devices to DMP:

dmpvios1\$ /usr/ios/cli/ioscli lsmap -all							
SVSA	Physloc	Client Partition ID					
	U9117.MMA.0686502-V2-C11						
VTD	vtscsi0						
Status	Available 8100000000000	00					
Backing device	hdisk21

VTD	vtscsi2						
Status	Available						
LUN	0x8300000000000000						
Backing device	hdisk18						
Physloc 002409A00000000	U789D.001.DQD04AF-P1-C5-	T1-W500507630813861A-L4					

The VIO Server has MPIO providing multi-pathing to these hdisks. The following commands show the configuration:

dmpvios1\$ lsdev -Cc disk | egrep "hdisk21|hdisk20|hdisk18"

hdisk18 Available 02-08-02 MPIO Other FC SCSI Disk Drive hdisk20 Available 02-08-02 MPIO Other FC SCSI Disk Drive hdisk21 Available 02-08-02 MPIO Other FC SCSI Disk Drive **5** Unconfigure all VTD devices from all virtual adapters on the system:

dmpviosl \$ **rmdev -p vhost0** vtscsi0 Defined vtscsi1 Defined vtscsi2 Defined

Repeat this step for all other virtual adapters.

6 Migrate the devices from MPIO to DMP.

Unmount the file system and varyoff volume groups residing on the MPIO devices.

Display the volume groups (vgs) in the configuration:

```
dmpvios1$ lsvg
rootvg
brunovg
dmpvios1 lsvg -p brunovg
brunovg:
PV_NAME PV STATE TOTAL PPs FREE PPs FREE DISTRIBUTION
hdisk19 active 511 501 103..92..102..102
hdisk22 active 511 501 103..92..102..102
```

Use the varyoffvg command on all affected vgs:

```
dmpvios1$ varyoffvg brunovg
```

Install the IBMDS8K ODM definition fileset to remove IBM MPIO support for IBM DS8K array LUNs.

dmpvios1\$ installp -aXd . devices.fcp.disk.ibm.rte

```
+-----+

- 9 Repeat step 1 through step 8 for VIO server2.
- **10** Start all of the VIO clients using HMC.

Migrating from PowerPath to DMP on a Virtual I/O server for a dual-VIOS configuration

This following example procedure illustrates a migration from PowerPath to DMP on the Virtual I/O server, in a configuration with two VIO Servers.

Example configuration values:

```
Managed System: dmpviosp6
VIO server1: dmpvios1
VIO server2: dmpvios2
VIO clients: dmpvioc1
SAN LUNS: EMC Clariion array
Current multi-pathing solution on VIO server: EMC PowerPath
```

To migrate dmpviosp6 from PowerPath to DMP

1 Before migrating, back up the Virtual I/O server to use for reverting the system in case of issues.

See the IBM website for information about backing up Virtual I/O server.

2 Shut down all of the VIO clients that are serviced by the VIO Server.

dmpvioc1\$ halt

3 Log into the VIO server partition.Use the following command to access the non-restricted root shell. All subsequent commands in this procedure must be invoked from the non-restricted shell.

\$ oem_setup_env

4 The following command shows lsmap output before migrating PowerPath VTD devices to DMP:

SVSA	Physloc	Client Partition ID
vhost0	U9117.MMA.0686502-V2-C11

- **9** Repeat step 1 to step 8 for VIO server2.
- **10** Start all of the VIO clients.

Configuring Dynamic Multi-Pathing (DMP) pseudo devices as virtual SCSI devices

DMP in the VIO server supports the following methods to export a device to the VIO client:

- DMP node method
 See "Exporting Dynamic Multi-Pathing (DMP) devices as virtual SCSI disks " on page 60.
- Logical partition-based method
 See "Exporting a Logical Volume as a virtual SCSI disk" on page 63.
- File-based method
 See "Exporting a file as a virtual SCSI disk" on page 65.

Exporting Dynamic Multi-Pathing (DMP) devices as virtual SCSI disks

DMP supports disks backed by DMP as virtual SCSI disks. Export the DMP device as a vSCSI disk to the VIO client.

To export a DMP device as a vSCSI disk

- 1 Log into the VIO server partition.
- 2 Use the following command to access the non-restricted root shell. All subsequent commands in this procedure must be invoked from the non-restricted shell.

```
$ oem_setup_env
```

3 The following command displays the DMP devices on the VIO server:

dmpvios1\$ lsdev -t dmpdisk

```
ibm_ds8000_0287AvailableVeritasDMPDeviceibm_ds8000_0288AvailableVeritasDMPDeviceibm_ds8000_0292AvailableVeritasDMPDeviceibm_ds8000_0293AvailableVeritasDMPDeviceibm_ds8000_029aAvailableVeritasDMPDeviceibm_ds8000_029aAvailableVeritasDMPDeviceibm_ds8000_02c1AvailableVeritasDMPDeviceibm_ds8000_0337AvailableVeritasDMPDevice
```

4 Assign the DMP device as a backing device. Exit from the non-restricted shell to run this command from the VIOS default shell.

```
dmpviosl$ exit
$ mkvdev -vdev ibm_ds8000_0288 -vadapter vhost0
vtscsi3 Available
```

- **5** Use the following command to display the configuration.
 - \$ lsmap -all

Physloc SVSA Client Partition ID _____ ____ U9117.MMA.0686502-V2-C11 0x0000000 vhost0 VTD vtscsi0 Available Status LUN 0x81000000000000000 Backing device ibm ds8000 0337 Physloc vtscsil VTD Available Status 0x82000000000000000 LUN Backing device ibm ds8000 02c1 Physloc vtscsi2 VTD Status Available 0x83000000000000000 LUN Backing device ibm ds8000 029a Physloc V TD vtscsi3 Available Status 0x84000000000000000 LUN Backing device ibm ds8000 0288 Physloc

- **6** For a dual-VIOS configuration, export the DMP device corresponding to the same SAN LUN on the second VIO Server in the configuration. To export the DMP device on the second VIO server, identify the DMP device corresponding to the SAN LUN as on the VIO Server1.
 - If the array supports the AVID attribute, the DMP device name is the same as the DMP device name on the VIO Server1.
 - Otherwise, use the UDID value of the DMP device on the VIO Server1 to correlate the DMP device name with same UDID on the VIO Server2. On VIO Server1:

```
$ oem_setup_env
```

dmpvios1\$ lsattr -El ibm_ds8000_0288

attribute value description user_settable dmpname ibm_ds8x000_0288 DMP Device name True pvid none Physical volume identifier True unique_id IBM%5F2107%5F75MA641%5F6005076308FFC61A00000000 0000288 Unique device identifier True

On VIO Server2:

\$ oem_setup_env

```
dmpvios2$ odmget -q "attribute = unique_id and

Exporting a Logical Volume as a virtual SCSI disk

Dynamic Multi-Pathing (DMP) supports vSCSI disks backed by a Logical Volume. Export the Logical Volume as a vSCSI disk to the VIO client.

To export a Logical Volume as a vSCSI disk

1 Create the volume group.

```
$ mkvg -vg brunovg ibm_ds8000_0292 ibm_ds8000_0293
brunovg
```

The following command displays the new volume group:

```
        $ lsvg -pv brunovg

        brunovg:

        PV_NAME
        PV STATE TOTAL PPs FREE PPs FREE DISTRIBUTION

        ibm_ds8000_0292 active
        494
        99..99..98..99..99

        ibm_ds8000_0293 active
        494
        494
        99..99..98..99..99
```

2 Make a logical volume in the volume group.

```
$ mklv -lv brunovg_lv1 brunovg 1G
brunovg lv1
```

The following command displays the new logical volume:

\$ lsvg -lv brunovg brunovg: LV NAME TYPE LPS PPS PVS LV STATE MOUNT POINT brunovg_lv1 jfs 256 256 1 closed/syncd N/A

3 Assign the logical volume as a backing device.

```
$ mkvdev -vdev brunovg_lv1 -vadapter vhost0
vtscsi4 Available
```

- **4** Use the following command to display the configuration.
 - \$ lsmap -all

Exporting a file as a virtual SCSI disk

Dynamic Multi-Pathing (DMP) supports vSCSI disks backed by a file. Export the file as a vSCSI disk to the VIO client.

To export a file as a vSCSI disk

1 Create the storage pool.

```
$ mksp brunospool ibm_ds8000_0296
brunospool
0516-1254 mkvg: Changing the PVID in the ODM.
```

2 Create a file system on the pool.

\$ mksp -fb bruno_fb -sp brunospool -size 500M bruno_fb File system created successfully. 507684 kilobytes total disk space. New File System size is 1024000

3 Mount the file system.

\$ mount

node	mounted	mounted over	vfs	date	options
/dev/hd4	/	jfs2	Jul 02	14:47	rw,log=/dev/hd8
/dev/hd2	/usr	jfs2	Jul 02	14:47	rw,log=/dev/hd8
/dev/hd9va	r /var	jfs2	Jul 02	14:47	rw,log=/dev/hd8

Extended attributes in VIO client for a virtual SCSI disk

Using Dynamic Multi-Pathing (DMP) in the a Virtual I/O server enables the DMP in the VIO Client to receive the extended attributes for the LUN. This enables the client LPAR to view back-end LUN attributes such as thin, SSD, and RAID levels associated with the vSCSI devices.

For more information about extended attributes and the prerequisites for supporting them, see the following tech note:

http://seer.entsupport.symantec.com/docs/337516.htm

Configuration prerequisites for providing extended attributes on VIO client for virtual SCSI disk

Dynamic Multi-Pathing (DMP) in VIO client will provide extended attributes information of backend SAN LUN. The following conditions are prerequisites for using extended attributes on the VIO client:

- VIO client has vSCSI disks backed by SAN LUNs.
- In the VIO Server partition, DMP is controlling those SAN LUNs.
- On VIO client, DMP is controlling the vSCSI disks.

Displaying extended attributes of virtual SCSI disks

When a VIO client accesses a virtual SCSI disk that is backed by a Dynamic Multi-Pathing (DMP) device on the a Virtual I/O server, the VIO client can access the extended attributes associated with the virtual SCSI disk.

The following commands can access and display extended attributes information associated with the vSCSI disk backed by DMP device on a Virtual I/O server.

- vxdisk -e list
- vxdmpadm list dmpnodename=<daname>
- vxdmpadm -v getdmpnode dmpnodename=<daname>
- vxdisk -p list <daname>

For example, use the following command on the VIO client dmpvioc1:

vxdisk -e list

DEVICE	TYPE	DISK	GROUP	STATUS	OS_NATIVE_NAME	ATTR
ibm_ds8x000_114f	auto:LVM	-	-	LVM	hdisk83	std
3pardata0_3968	auto:aixdisk	-	-	online thin	hdisk84	tp

vxdmpadm list dmpnode dmpnodename=3pardata0_3968

Chapter

Administering DMP

This chapter includes the following topics:

- About enabling and disabling I/O for controllers and storage processors
- About displaying DMP database information
- Displaying the paths to a disk
- Setting customized names for DMP nodes
- Configuring DMP for SAN booting
- Administering the root volume group (rootvg) under DMP control
- Using Storage Foundation in the logical partition (LPAR) with virtual SCSI devices
- Running alt_disk_install, alt_disk_copy and related commands on the OS device when DMP native support is enabled
- Administering DMP using the vxdmpadm utility

About enabling and disabling I/O for controllers and storage processors

DMP lets you to turn off I/O through a Host Bus Adapter (HBA) controller or the array port of a storage processor so that you can perform administrative operations. This feature can be used when you perform maintenance on HBA controllers on the host, or array ports that are attached to disk arrays supported by DMP. I/O operations to the HBA controller or the array port can be turned back on after the maintenance task is completed. You can accomplish these operations using the vxdmpadm command.

For Active/Active type disk arrays, when you disable the I/O through an HBA controller or array port, the I/O continues on the remaining paths. For Active/Passive

type disk arrays, if disabling I/O through an HBA controller or array port resulted in all primary paths being disabled, DMP will failover to secondary paths and I/O will continue on them.

After the administrative operation is over, use the vxdmpadm command to re-enable the paths through the HBA controllers or array ports.

See "Disabling I/O for paths, controllers, array ports, or DMP nodes" on page 137.

See "Enabling I/O for paths, controllers, array ports, or DMP nodes" on page 139.

You can also perform certain reconfiguration operations dynamically online.

See "About online Dynamic Reconfiguration " on page 171.

About displaying DMP database information

You can use the vxdmpadm command to list DMP database information and perform other administrative tasks. This command allows you to list all controllers that are connected to disks, and other related information that is stored in the DMP database. You can use this information to locate system hardware, and to help you decide which controllers need to be enabled or disabled.

The vxdmpadm command also provides useful information such as disk array serial numbers, which DMP devices (disks) are connected to the disk array, and which paths are connected to a particular controller, enclosure, or array port.

See "Administering DMP using the vxdmpadm utility" on page 108.

Displaying the paths to a disk

The vxdisk command is used to display the multi-pathing information for a particular metadevice. The metadevice is a device representation of a physical disk having multiple physical paths through the system's HBA controllers. In Dynamic Multi-Pathing (DMP,) all the physical disks in the system are represented as metadevices with one or more physical paths.

To display the multi-pathing information on a system

• Use the vxdisk path command to display the relationships between the device paths, disk access names, disk media names, and disk groups on a system as shown here:

```
# vxdisk path
```

•

SUBPATH	DANAME	DMNAME	GROUP	STATE
hdisk1	hdisk1	mydg01	mydg	ENABLED
hdisk9	hdisk9	mydg01	mydg	ENABLED
hdisk2	hdisk2	mydg02	mydg	ENABLED
hdisk10	hdisk10	mydg02	mydg	ENABLED

This shows that two paths exist to each of the two disks, mydg01 and mydg02, and also indicates that each disk is in the ENABLED state.

To view multi-pathing information for a particular metadevice

1 Use the following command:

```
# vxdisk list devicename
```

For example, to view multi-pathing information for hdisk18, use the following command:

```
# vxdisk list hdisk18
```

The output from the vxdisk list command displays the multi-pathing information, as shown in the following example:

```
Device: hdisk18
devicetag: hdisk18
type: simple
hostid: sys1
.
.
Multipathing information:
numpaths: 2
hdisk18 state=enabled type=primary
hdisk26 state=disabled type=secondary
```

The numpaths line shows that there are 2 paths to the device. The next two lines in the "Multipathing information" section of the output show that one path is active (state=enabled) and that the other path has failed (state=disabled).

The ${\tt type}$ field is shown for disks on Active/Passive type disk arrays such as the EMC CLARiiON, Hitachi HDS 9200 and 9500, Sun StorEdge 6xxx, and Sun StorEdge T3 array. This field indicates the primary and secondary paths to the disk.

The type field is not displayed for disks on Active/Active type disk arrays such as the EMC Symmetrix, Hitachi HDS 99xx and Sun StorEdge 99xx Series, and IBM ESS Series. Such arrays have no concept of primary and secondary paths.

2 Alternately, you can use the following command to view multi-pathing information:

vxdmpadm getsubpaths dmpnodename=devicename

For example, to view multi-pathing information for emc_clariion0_17, use the following command:

vxdmpadm getsubpaths dmpnodename=emc_clariion0_17

Typical output from the vxdmpadm getsubpaths command is as follows:

NAME	STATE [A]	PATH-TYPE[M]	CTLR-NAME	ENCLR-TYPE	ENCLR-NAME	ATTRS
hdisk107	ENABLED(A)	PRIMARY	fscsi1	EMC_CLARiiON	emc_clariion0	-
hdisk17	ENABLED	SECONDARY	fscsi0	EMC_CLARiiON	emc_clariion0	-
hdisk2	ENABLED	SECONDARY	fscsi0	EMC_CLARiiON	emc_clariion0	-
hdisk32	ENABLED(A)	PRIMARY	fscsi0	EMC_CLARiiON	emc_clariion0	-

Setting customized names for DMP nodes

The Dynamic Multi-Pathing (DMP) node name is the metadevice name that represents the multiple paths to a disk. The Device Discovery Layer (DDL) generates the DMP node name from the device name according to the Dynamic Multi-Pathing (DMP) naming scheme.

See "Disk device naming in DMP" on page 24.

You can specify a customized name for a DMP node. User-specified names are persistent even if names persistence is turned off.

You cannot assign a customized name that is already in use by a device. However, if you assign names that follow the same naming conventions as the names that the DDL generates, a name collision can potentially occur when a device is added. If the user-defined name for a DMP device is the same as the DDL-generated name for another DMP device, the vxdisk list command output displays one of the devices as 'error'.

To specify a custom name for a DMP node

- Use the following command:
 - # vxdmpadm setattr dmpnode dmpnodename name=name

You can also assign names from an input file. This enables you to customize the DMP nodes on the system with meaningful names.

To specify a custom name for an enclosure

Use the following command:

vxdmpadm setattr enclosure enc_name name=custom_name

To assign DMP nodes from a file

1 To obtain a file populated with the names of the devices in your configuration, use the following command:

vxddladm -1 assign names > filename

The sample file shows the format required and serves as a template to specify your customized names.

You can also use the script vxgetdmpnames to get a sample file populated from the devices in your configuration.

- 2 Modify the file as required. Be sure to maintain the correct format in the file.
- **3** To assign the names, specify the name and path of the file to the following command:

vxddladm assign names file=pathname

To clear custom names

 To clear the names, and use the default operating system-based naming or enclosure-based naming, use the following command:

vxddladm -c assign names

Configuring DMP for SAN booting

On AIX, you can configure a SAN disk for booting the operating system. Such a disk, called a SAN boot disk, contains the root volume group (rootvg). In order for the SAN disk to be used for booting (bootable), the SAN disk must be a Logical Volume Manager (LVM) disk. The SAN root disk must be an Active/Active (A/A), A/A-A, or ALUA type array.

You can configure a SAN boot disk so that Dynamic Multi-Pathing (DMP) provides the multi-pathing for this device.

DMP supports LVM root disks in the following ways:

DMP support for OS native LVM disks

When you enable the support for LVM disks, DMP provides multi-pathing functionality for the operating system native devices configured on the system. When this option is enabled, operations such as extendvg and mirrorvg can be done online.

DMP native support is controlled by the tunable parameter dmp_native_support. Symantec recommends this method.

See "About setting up DMP to manage native devices" on page 29.

DMP support for LVM root disks
 When you enable the support for LVM root disks only, DMP manages the multi-pathing for the LVM root disk only.

LVM root disk support is controlled with the command: vxdmpadm native enable|disable vgname=rootvg

The procedures in this section describe configuring a SAN root disk under DMP control. Choose the appropriate method based on the existing configuration, as follows:

Configure a new device.	See "Configuring DMP support for booting over a SAN" on page 75.
Migrate an internal root disk.	See "Migrating an internal root disk to a SAN root disk under DMP control " on page 78.
Migrate an existing SAN root disk under MPIO control	See "Migrating a SAN root disk from MPIO to DMP control" on page 83.
Migrate an existing SAN root disk under EMC PowerPath control	See "Migrating a SAN root disk from EMC PowerPath to DMP control" on page 84.

After you configure the root disk as a SAN root disk under DMP control, administer the root volume group.

See "Administering the root volume group (rootvg) under DMP control" on page 84.

Configuring DMP support for booting over a SAN

For DMP to work with an LVM root disk over a SAN, configure the system to use the boot device over all possible paths.

To configure DMP support for booting over a SAN

Verify that each path to the root device has the same physical volume identifier (PVID) and the same volume group. Use the LSPV command for the root volume group to verify that the PVID and volume group entries are set correctly. The PVID and volume group entries in the second and third columns of the output should be identical for all the paths.

In this example, the LVM root disk is multi-pathed with four paths. The output from the lspv command for the root volume group (rootvg) is as follows:

```
# lspv | grep rootvg
hdisk374 00cbf5ce56def54d rootvg active
hdisk375 00cbf5ce56def54d rootvg active
hdisk376 00cbf5ce56def54d rootvg active
hdisk377 00cbf5ce56def54d rootvg active
```

2 If the PVID and volume group entries are not set correctly on any of the paths, use the chdev command to set the correct value.

For example, the following output shows that the hdisk377 path is not set correctly:

```
# lspv
hdisk374 00cbf5ce56def54d rootvg active
hdisk375 00cbf5ce56def54d rootvg active
hdisk376 00cbf5ce56def54d rootvg active
hdisk377 none None
```

To set the PVID for the path, use the following command:

```
# chdev -1 hdisk377 -a pv=yes
hdisk377 changed
```

The output of the lspv command now shows the correct values:

```
# lspv | grep rootvg
hdisk374 00cbf5ce56def54d rootvg active
hdisk375 00cbf5ce56def54d rootvg active
hdisk376 00cbf5ce56def54d rootvg active
hdisk377 00cbf5ce56def54d rootvg active
```

- **3** If any path to the target disk has SCSI reserve ODM attribute set, then change the attributes to release the SCSI reservation from the paths, on a restart.
 - If a path has the reserve_policy attribute set, change thereserve_policy attribute to no_reserve for all the paths.

```
# lsattr -E1 hdisk557 | grep res
reserve_policy single_path
Reserve Policy True
# chdev -1 hdisk557 -a reserve_policy=no_reserve -P
hdisk557 changed
If a path has the reserve_lock attribute set, change the
reserve_lockattribute to no.
# lsattr -E1 hdisk558 | grep reserve_lock
reserve_lock yes
```

Reserve Device on open True # chdev -1 hdisk558 -a reserve_lock=no -P

hdisk558 changed

4 Set the boot list to include all the paths of current boot disk.

```
# bootlist -m normal hdisk374 hdisk375 hdisk376 hdisk377 blv=hd5
```

Verify that the boot list includes all paths and that each path shows the default boot volume hd5:

```
# bootlist -m normal -o
hdisk374 blv=hd5
hdisk375 blv=hd5
hdisk376 blv=hd5
hdisk377 blv=hd5
```

5 If the blv option is not set for a path to the disk, use the bootlist command to set it. For example:

bootlist -m normal hdisk374 hdisk375 hdisk376 hdisk377 blv=hd5

- 6 Run one of the following commands to configure DMP on the root disk:
 - The recommended method is to turn on DMP support for LVM volumes, including the root volume.

vxdmpadm settune dmp_native_support=on

 The following command enables DMP support for LVM volumes only for the root disk.

vxdmpadm native enable vgname=rootvg

- 7 Reboot the system. DMP takes control of the SAN boot device to perform load balancing and failover.
- 8 Verify whether DMP controls the root disk.

# vxdmpadm	native list vgname=rootvg
PATH	DMPNODENAME
hdisk374	ams_wms0_491
hdisk375	ams_wms0_491
hdisk376	ams_wms0_491
hdisk377	ams_wms0_491

lspv | grep rootvg

hdisk374 00cbf5ce56def54d rootvg active hdisk375 00cbf5ce56def54d rootvg active hdisk376 00cbf5ce56def54d rootvg active hdisk377 00cbf5ce56def54d rootvg active

Migrating an internal root disk to a SAN root disk under DMP control

If the system has been booted from an internal disk (such as hdisk0), you can configure an alternate root disk on the attached SAN storage before you put it under DMP control.

In this example, a SAN boot disk with multiple paths is created by cloning the existing root disk, and then enabling multi-pathing support by DMP.

To migrate an internal root disk to a SAN root disk under DMP control

1 Choose a disk to use for the SAN root disk. If the disk is under VM control, then remove the disk from VM control before proceeding:.

```
# vxdiskunsetup ams_wms0_1
```

```
# vxdisk rm ams wms0 1
```

2 Clear the PVIDs of all the paths to the SAN boot disk. If the SAN disk is under VM control, then you can get multi-pathing information using the vxdmpadm command:

Clear the PVIDs of all these paths.

```
# chdev -1 hdisk542 -a pv=clear
hdisk542 changed
# chdev -1 hdisk557 -a pv=clear
hdisk557 changed
# chdev -1 hdisk558 -a pv=clear
hdisk558 changed
# chdev -1 hdisk559 -a pv=clear
hdisk559 changed
```

Note that unless the disk is under VM control, the clear command may not work for secondary paths.

- **3** If any path to the target disk has SCSI reserve ODM attribute set, then change the attributes to release the SCSI reservation from the paths, on a restart.
 - If a path has the reserve_policy attribute set, change the reserve_policy attribute to no reserve for all the paths.

```
# lsattr -E1 hdisk557 | grep res
reserve_policy single_path
Reserve Policy True
```

chdev -1 hdisk557 -a reserve_policy=no_reserve -P
hdisk557 changed

 If a path has the reserve_lock attribute set, change the reserve_lock attribute to no.

lsattr -E1 hdisk558 | grep reserve_lock
reserve_lock yes
Reserve Device on open True
chdev -1 hdisk558 -a reserve_lock=no -P
hdisk558 changed

4 Use the alt_disk_install command to clone the rootvg to the SAN boot disk. You can use any of the paths, but preferably use the primary path.

```
# alt disk install -C -P all hdisk542
+-----+
ATTENTION: calling new module /usr/sbin/alt disk copy. Please
see the
alt disk copy man page and documentation for more details.
Executing command: /usr/sbin/alt disk copy -P "all" -d
"hdisk542"
+-----+
Calling mkszfile to create new /image.data file.
Checking disk sizes.
Creating cloned rootvg volume group and associated logical
volumes.
Creating logical volume alt hd5.
Creating logical volume alt hd6.

for backup and restore into the alternate file system ...
Backing-up the rootvg files and restoring them to the alternate
file system...
Modifying ODM on cloned disk.
Building boot image on cloned disk.
forced unmount of /alt inst/var
forced unmount of /alt inst/usr
forced unmount of /alt inst/tmp
forced unmount of /alt inst/opt
forced unmount of /alt inst/home
forced unmount of /alt inst
```

```
forced unmount of /alt_inst
Changing logical volume names in volume group descriptor area.
Fixing LV control blocks...
Fixing file system superblocks...
Bootlist is set to the boot disk: hdisk542
```

5 Use the lspv command to confirm that the altinst_rootvg has been created for one of the paths to the SAN disk:

```
# lspv | grep rootvg
hdisk125 00cdee4fd0e3b3da rootvg active
hdisk542 00cdee4f5b103e98 altinst rootvg
```

6 Update the remaining paths to the SAN disk to include the correct altinst_rootvg information:

```
# chdev -l hdisk557 -a pv=yes
hdisk557 changed
# chdev -l hdisk558 -a pv=yes
hdisk558 changed
# chdev -l hdisk559 -a pv=yes
hdisk559 changed
# lspv | grep rootvg
hdisk125 00cdee4fd0e3b3da rootvg active
hdisk542 00cdee4f5b103e98 altinst_rootvg
hdisk558 00cdee4f5b103e98 altinst_rootvg
hdisk559 00cdee4f5b103e98 altinst_rootvg
hdisk59 00cdee4f5b105b104e98 altinst_rootvg
hdisk59 00cdee4f5b104e98 altinst_rootvg
```

7 The **bootlist** command verifies that the boot device has been updated for only one of the paths to the SAN disk:

```
# bootlist -m normal -o
hdisk542 blv=hd5
```

8 Use the **bootlist** command to include the other paths to the new boot device:

```
# bootlist -m normal hdisk542 hdisk557 hdisk558 hdisk559 blv=hd5
# bootlist -m normal -o
hdisk542 blv=hd5
hdisk557 blv=hd5
hdisk559 blv=hd5
hdisk559 blv=hd5
```

- 9 Reboot the system from the SAN disk.
- **10** Enable DMP on the root disk, using one of the following commands.
 - The recommended method is to turn on DMP support for LVM volumes, including the root volume.

```
# vxdmpadm settune dmp_native_support=on
```

 The following command enables DMP support for LVM volumes only for the root disk. This method will be deprecated in a future release.

```
# vxdmpadm native enable vgname=rootvg
```

- 11 Reboot the system to enable DMP rootability.
- **12** Confirm that the system is booted from the new multi-pathed SAN disk. Use the following commands:

```
# bootinfo -b
hdisk542
# bootlist -m normal -o
hdisk542 blv=hd5
hdisk557 blv=hd5
hdisk558 blv=hd5
hdisk559 blv=hd5
# lspv | grep rootvg
hdisk125 00cdee4fd0e3b3da old_rootvg
ams wms0 1 00cdee4f5b103e98 rootvg active
```

13 Verify whether DMP controls the root disk..

Migrating a SAN root disk from MPIO to DMP control

If the system has been booted from a SAN disk under MPIO control, MPIO must be disabled before DMP control can be enabled.

To migrate a SAN root disk from MPIO to DMP control

1 Disable MPIO by installing a device-specific ODM definition fileset as described in the following Technote:

http://www.symantec.com/docs/TECH227105

- 2 Reboot the system. The system is booted without any multi-pathing support.
- 3 Configure DMP.

See "Configuring DMP support for booting over a SAN" on page 75.

Migrating a SAN root disk from EMC PowerPath to DMP control

If the system has a root volume group (rootvg) under EMC PowerPath control, use this procedure to migrate the rootvg to DMP control.

To migrate a SAN root disk from EMC PowerPath to DMP control

- 1 Remove the PowerPath device corresponding to the root disk (rootvg) from VxVM control:
 - # vxdisk rm hdiskpowerX
- 2 Issue the following command so that PowerPath returns the pvid to the hdisk device. Otherwise the bosboot command does not succeed.

pprootdev fix

3 Remove the device from PowerPath so that PowerPath releases control of the boot device on the next reboot.

powermt unmanage dev=hdiskpowerX

4 Enable DMP root support.

See "Configuring DMP support for booting over a SAN" on page 75.

5 Reboot the system. The system is booted with the rootvg under DMP control.

Administering the root volume group (rootvg) under DMP control

After the root disk is configured for DMP control, the device is visible as the root volume group (rootvg) to the operating system. DMP controls the paths to the device. For certain maintenance tasks, the operating system needs to access the

underlying paths. DMP provides a method to release the paths to the OS during those operations, and resume control of the paths after the operations complete.

The following sections give the procedures for common administrative tasks.

Running the bosboot command after installing software.	See "Running the bosboot command when LVM rootvg is enabled for DMP" on page 85.
Extending the root volume group.	See "Extending an LVM rootvg that is enabled for DMP" on page 86.
Reducing the root volume group.	See "Reducing the native rootvg that is enabled for DMP" on page 90.
Mirroring the root volume group.	See "Mirroring the root volume group" on page 92.
Removing the mirror for the root volume group.	See "Removing the mirror for the root volume group (rootvg)" on page 93.
Cloning the root volume group.	See " Cloning a LVM rootvg that is enabled for DMP" on page 95.
Using the mksysb command	See "Using mksysb when the root volume group is under DMP control" on page 100.

Running the bosboot command when LVM rootvg is enabled for DMP

You may want to use the bosboot command while performing certain tasks. For example, many software installations require running the bosboot command at the end of installation.

To run bosboot command on the rootvg

1 Determine the device paths of the rootvg that are under DMP control.

<pre># vxdmpadm native list</pre>						
PATH	DMPNODENAME					
hdisk168	emc0_0039					
hdisk172	emc0_0039					
hdisk184	emc0_0039					
hdisk188	emc0_0039					

lspv | grep -w rootvg

hdisk168	00c398edf9fae077	rootvg	active
hdisk172	00c398edf9fae077	rootvg	active
hdisk184	00c398edf9fae077	rootvg	active
hdisk188	00c398edf9fae077	rootvg	active

2 Run the operation that requires the bosboot command; for example, install the software. Alternatively, run the bosboot command manually.

```
# bosboot -ad /dev/ipldevice
bosboot: Boot image is 56863 512 byte blocks.
```

If the bosboot command fails on /dev/ipldevice, then retry the command on the paths of current boot disk until it succeeds.

Extending an LVM rootvg that is enabled for DMP

When an LVM root volume group (rootvg) is enabled for DMP, you can add DMP devices to the rootvg.

The procedure differs depending on whether or not DMP support for native devices is enabled; that is, whether the dmp_native_support tunable is set to on.

If dmp_native_support is on, and an LVM root See "Extending an LVM rootvg when volume group (rootvg) is enabled for DMP dmp_native_support is on " on page 86.

If dmp_native_support is off, and an LVM root See "Extending an LVM rootvg when volume group (rootvg) is enabled for DMP dmp_native_support is off" on page 88.

Extending an LVM rootvg when dmp_native_support is on

If dmp_native_support is on, and an LVM root volume group (rootvg) is enabled for DMP, you can add DMP devices online to the rootvg, without rebooting the system.

To add a DMP device to a DMP-enabled rootvg

1 List the available physical volumes. The output includes the DMP devices that are available to LVM. For example:

```
# lsdev -c disk
...
ibm_ds8x000_0100 Available Veritas DMP Device
ibm_ds8x000_017d Available Veritas DMP Device
emc0_00a5 Available Veritas DMP Device
emc0_00a7 Available Veritas DMP Device
```

2 List the paths that are configured to be managed by DMP as a result of enabling DMP support for the volume group. You can optionally specify the volume group name using the *vgname* parameter.

3 List the volume groups:

```
# lspv
```

```
        hdisk1
        00f617b700039215
        None

        hdisk24
        00f617b700039215
        None

        hdisk21
        00f617b7ae6f71b3
        rootvg active

        hdisk22
        00f617b7ae6f71b3
        rootvg active
```

4 Extend the DMP-enabled rootvg to an additional DMP device. For example:

```
# extendvg rootvg ibm_ds8x000_017d
```

5 Verify the subpaths of the DMP device.

6 Release the paths to the operating system.

```
# vxdmpadm native release
```

7 Verify that the DMP device is added to the rootvg. For example:

# lsvg -p rootvg							
rootvg:							
PV_NAME	PV STATE	TOTAL PPs	FREE PPs	FREE DISTRIBUTION			
hdisk21	active	73	0	0000000000			
hdisk1	active	15	15	0303030303			

8 Verify that the subpaths of the DMP device are added to the rootvg.

```
# lspv | grep -w rootvg
hdisk1 00f617b700039215 rootvg active
hdisk21 00f617b7ae6f71b3 rootvg active
hdisk22 00f617b7ae6f71b3 rootvg active
hdisk24 00f617b700039215 rootvg active
```

Extending an LVM rootvg when dmp_native_support is off

When an LVM root volume group (rootvg) is enabled for DMP, you can extend the rootvg by adding a SAN disk. If the root support is enabled with the vxdmpadm native enable command, the system must be rebooted before DMP can manage the new devices added to the LVM rootvg. In this case, the only DMP devices available to LVM are the devices in the rootvg. Therefore, you must extend the rootvg over the OS device paths. After the reboot, DMP can service the I/O to the new devices that were added to the LVM rootvg.

To add a SAN disk to a DMP-enabled rootvg

- 1 If the disk is under VxVM control, remove the disk from VxVM before you continue.
 - # vxdisk rm emc0_00a7
- 2 Clear the physical volume Identifiers (PVIDs) of all the paths to the SAN disk. Perform this step for each of the paths.

vxdmpadm getsubpaths dmpnodename=emc0_00a7

NAME	STATE [A]	PATH-TYPE[M]	CTLR-NAME	ENCLR-TYPE	ENCLR-NAME	ATTRS
hdisk32	ENABLED(A)	-	fscsi0	EMC	emc0	-
hdisk6	ENABLED(A)	-	fscsi0	EMC	emc0	-
hdisk88	ENABLED(A)	-	fscsi1	EMC	emc0	-
hdisk99	ENABLED(A)	-	fscsi1	EMC	emc0	-

For example:

chdev -1 hdisk32 -a pv=clear

- **3** Update the PVID on the remaining paths of the added SAN disk. Perform this step for each of the paths.
 - # chdev -1 hdisk6 -a pv=yes
 - # chdev -1 hdisk88 -a pv=yes
 - # chdev -1 hdisk99 -a pv=yes
- 4 Add the SAN disk to the DMP-enabled rootvg.
 - # extendvg rootvg hdisk32
- **5** Reboot the system.
 - # reboot

6 Verify the DMP rootvg configuration.

vxdmpadm native list

PATH	DMPNODENAME
hdisk143	emc0_0039
hdisk142	emc0_0039
hdisk141	emc0_0039
hdisk127	emc0_0039
hdisk32	emc0_00a7
hdisk6	emc0_00a7
hdisk88	emc0_00a7
hdisk99	emc0_00a7
hdisk127 hdisk32 hdisk6 hdisk88	emc0_0039 emc0_00a7 emc0_00a7 emc0_00a7

7 Verify that the DMP device is added to the rootvg. For example:

# lsvg -p rootvg							
rootvg:							
PV_NAME	PV STATE	TOTAL	PPs	FREE	PPs	FREE DISTRIBUTION	
hdisk143	active	73		0		00000000	
hdisk88	active	15		15		0303030303	
# lspv gı	rep -w rootvo	3					
hdisk143	00c398ed0000)8e79	rootv	7g	active		
hdisk142	00c398ed0000)8e79	root	7g	active		
hdisk141	00c398ed0000)8e79	root	7g	active		
hdisk127	00c398ed0000)8e79	root	7g	active		
hdisk32	00c398edf9fa	ae077	rootv	7g	active		
hdisk6	00c398edf9fa	ae077	rootv	7g	active		
hdisk88	00c398edf9fa	ae077	rootv	7g	active		
hdisk99	00c398edf9fa	ae077	rootv	7g	active		

Reducing the native rootvg that is enabled for DMP

When a native root volume group (rootvg) is enabled for DMP, and contains multiple SAN disks, you can reduce the rootvg. Use this procedure to remove a SAN disk from a rootvg that includes multiple SAN disks. This procedure can be done online, without requiring a reboot.

To remove a SAN disk from a DMP-enabled rootvg

1 View the rootvg configuration. If the configuration contains multiple SAN disks, you can remove one.

# lsvg -p rootvg								
PV_NAME	PV STATE	TOTAL PPs	FREE PPs	FREE DISTRIBUTION				
hdisk1	active	73	8	0000000008				
hdisk21	active	15	15	0303030303				
# lspv grep -w rootvg hdisk1 00c398edf9fae077 rootvg active								
hdisk21	00c398ed0	0008e79	rootvg	active				
hdisk22	00c398ed0	0008e79	rootvg	active				
hdisk24	00c398edf	9fae077	rootvg	active				

2 Run the following comand to acquire the PVIDs from the operating system:

vxdmpadm native acquire

3 The lspv output now displays the DMP node names, instead of the device paths:

# lspv grep ·	-w rootvg		
emc0_0039	00c398ed00008e79	rootvg	active
emc0_00a7	00c398edf9fae077	rootvg	active

4 Remove the SAN disk from the DMP-enabled rootvg. If the physical volume has allocated partitions, you must move or delete the partitions before you remove the SAN disk.

reducevg rootvg emc0 00a7

5 Verify that the DMP device is removed from the DMP rootvg configuration. For example:

# lsvg -p rootvg					
PV_NAME	PV STATE	TOTAL PP	s FREE PPs	FREE DISTRIBUTION	
emc0_0039	active	73	8	0000000008	
# lspv grep -w rootvg					
emc0 0039	00c398ed00	008e79	rootvq	active	

6 Run the following comand to release the PVIDs to the operating system:

```
# vxdmpadm native release
```

7 The lspv output now displays the device paths:

# lspv	grep -w rootvg		
hdisk22	00c398ed00008e79	rootvg	active
hdisk21	00c398ed00008e79	rootvg	active

Mirroring the root volume group

You may want to create a mirror of the root volume group to add redundancy. For a root volume group that DMP controls, use the operating system commands to create the mirror.

To mirror a root volume group

1 Extend the DMP-enabled rootvg to a second DMP device.

See "Extending an LVM rootvg that is enabled for DMP" on page 86.

If the rootvg is already extended over DMP device using the recommended steps, then go to step 2.

2 Create the mirror of the root volume group.

```
# mirrorvg rootvg
0516-1734 mklvcopy: Warning, savebase failed. Please manually
run 'savebase' before rebooting.
....
0516-1804 chvg: The quorum change takes effect immediately.
0516-1126 mirrorvg: rootvg successfully mirrored, user should
        perform bosboot of system to initialize boot records.
        Then, user must modify bootlist to include: hdisk74 hdisk70.
```

3 As the output of the mirrorvg command indicates, run the savebase command on /dev/ipldevice. If the savebase command returns a non-zero value, then retry the command on the paths of current boot disk (hdisk70, hdisk72) until it succeeds.

```
# savebase -d /dev/ipldevice
# echo $?
0
```

4 As the output of the mirrorvg command indicates, run the bosboot command to initialize the boot records. If the bosboot command fails on /dev/ipldevice, then retry the command on the paths of current boot disk until it succeeds.

```
# bosboot -ad /dev/ipldevice
A previous bosdebug command has changed characteristics of this
boot image. Use bosdebug -L to display what these changes are.
```

bosboot: Boot image is 56863 512 byte blocks.

5 Include the paths corresponding to the mirror device in the boot list. In this example, hdisk70 and hdisk72 are the original boot disk. Add the paths for hdisk73 and hdisk74.

```
# bootlist -m normal -o
hdisk70 blv=hd5
hdisk72 blv=hd5
# bootlist -m normal hdisk70 hdisk72 hdisk73 hdisk74 blv=hd5
# bootlist -m normal -o
hdisk70 blv=hd5
hdisk72 blv=hd5
hdisk73 blv=hd5
hdisk74 blv=hd5
```

6 Verify the rootvg.

Removing the mirror for the root volume group (rootvg)

To remove redundancy to the root volume group, remove the mirror of the root volume group. For a root volume group that is under DMP control, use the operating system commands to remove the mirror.

To unmirror the root volume group

1 View the configuration of the root volume group.

lspv | grep -w rootvg

```
hdisk70 00f60bfea7406c01 rootvg active
hdisk72 00f60bfea7406c01 rootvg active
hdisk73 00f60bfe000d0356 rootvg active
hdisk74 00f60bfe000d0356 rootvg active
```

2 Remove the mirror from the root volume group.

unmirrorvg rootvg

0516-1246 rmlvcopy: If hd5 is the boot logical volume, please run 'chpv -c <diskname>' as root user to clear the boot record and avoid a potential boot off an old boot image that may reside on the disk from which this logical volume is moved/removed. 0516-1804 chvg: The quorum change takes effect immediately. 0516-1144 unmirrorvg: rootvg successfully unmirrored, user should perform bosboot of system to reinitialize boot records. Then, user must modify bootlist to just include: hdisk70.

3 As the output of the unmirrorvg command in step 2 indicates, run the chpv -c command on the paths of the device that formerly was the mirror. In this example, the paths are hdisk73 and hdisk74.

```
# chpv -c hdisk74
```

```
# chpv -c hdisk73
```

4 Set the boot list to remove the paths for the former mirror. In this example, remove the paths for hdisk73 and hdisk74. The boot list includes the paths hdisk70 and hdisk72.

```
# bootlist -m normal -o
hdisk70 blv=hd5
hdisk72 blv=hd5
hdisk73 blv=hd5
hdisk74 blv=hd5
# bootlist -m normal hdisk70 hdisk72 blv=hd5
# bootlist -m normal -o
hdisk70 blv=hd5
hdisk72 blv=hd5
```

5 As the output of the unmirrorvg command in step 2 indicates, run bosboot command to reflect the changes. If the bosboot command fails on /dev/ipldevice, then retry the command on the paths of current boot disk until it succeeds.

```
# bosboot -ad /dev/ipldevice
A previous bosdebug command has changed characteristics of this
boot image. Use bosdebug -L to display what these changes are.
bosboot: Boot image is 56863 512 byte blocks.
```

6 Verify that the mirror of the rootvg is removed.

Cloning a LVM rootvg that is enabled for DMP

Use the <code>alt_disk_install</code> command to clone an LVM rootvg that is enabled for DMP.

To clone an LVM rootvg that is enabled for DMP

1 Show the DMP node names.

```
# vxdmpadm native list
```

PATH	DMPNODENAME
hdisk75	ams_wms0_491
hdisk76	ams_wms0_491
hdisk80	ams_wms0_491
hdisk81	ams_wms0_491

2 Verify that the DMP node is the rootvg.

```
# lspv | grep -w rootvg
hdisk75 00c408c4dbd98818 rootvg active
hdisk76 00c408c4dbd98818 rootvg active
hdisk80 00c408c4dbd98818 rootvg active
hdisk81 00c408c4dbd98818 rootvg active
```

3 Show the DMP paths for the target disk.

```
# vxdmpadm getsubpaths dmpnodename=emc_clariion0_137
```

```

Bootlist is set to the boot disk: hdisk59 blv=hd5
```

6 Set the boot list to include all the paths to emc_clariion0_137.

bootlist -m normal hdisk59 hdisk62 hdisk65 hdisk68 blv=hd5

Verify that the boot list includes all paths and that each path shows the default boot volume hd5:

```
# bootlist -m normal -o
hdisk59 blv=hd5
hdisk62 blv=hd5
hdisk65 blv=hd5
hdisk68 blv=hd5
```

7 Reboot the system.

```
# reboot
Rebooting . . .
```

8 Verify the DMP configuration.

<pre># vxdmpadm native list</pre>	
PATH	DMPNODENAME
hdisk59	emc_clariion0_137
hdisk62	emc_clariion0_137
hdisk65	emc_clariion0_137
hdisk68	emc_clariion0_137

9 Verify the lspv output shows the path names.

```
# lspv | grep -w rootvg
hdisk59 00c408c4cc6f264e rootvg active
hdisk62 00c408c4cc6f264e rootvg active
hdisk65 00c408c4cc6f264e rootvg active
hdisk68 00c408c4cc6f264e rootvg active
```

Cleaning up the alternate disk volume group when LVM rootvg is enabled for DMP

When the LVM rootvg is enabled for DMP, use the procedures in this section to clean up the alternate disk volume group. The clean-up process removes the alternate root volume group (altinst_rootvg) from the AIX Object Data Manager (ODM) database. After you clean up the alternate disk volume group, the lspv command output displays 'None' for the altinst_rootvg. The command does not remove any data from the disk.

To clean up the alternate disk volume group when LVM rootvg is enabled for DMP

1 Verify that LVM rootvg is enabled for DMP. The alternate disk volume group to be cleaned up is altinst_rootvg.

# lspv grep 1	cootvg	
hdisk59	00c408c4cc6f264e	rootvg active
hdisk62	00c408c4cc6f264e	rootvg active
hdisk65	00c408c4cc6f264e	rootvg active
hdisk68	00c408c4cc6f264e	rootvg active
ams_wms0_491	00c408c4dbd98818	altinst_rootvg

2 Show the DMP node names.

vxdmpadm native list

PATH	DMPNODENAME
hdisk59	emc_clariion0_137
hdisk62	emc_clariion0_137
hdisk65	emc_clariion0_137
hdisk68	emc_clariion0_137

3 Clean up the alternate disk volume group, altinst_rootvg.

alt_disk_install -X altinst_rootvg

4 Display the configuration.

# lspv gr	ep rootvg	
hdisk59	00c408c4cc6f264e	rootvg active
hdisk62	00c408c4cc6f264e	rootvg active
hdisk65	00c408c4cc6f264e	rootvg active
hdisk68	00c408c4cc6f264e	rootvg active

Using mksysb when the root volume group is under DMP control

You can create a mksysb image of the client. You can use the mksysb image to restore the root volume group, or to install on another client using NIM.

When the root volume group is under DMP control, use the following procedure to create the mksysb image.

To use mksysb when the root volume group is enabled for DMP

1 Show the DMP node names.

<pre># vxdmpadm native</pre>	list
PATH	DMPNODENAME
hdisk70	ams_wms0_491
hdisk72	ams_wms0_491
hdisk73	ams_wms0_491
hdisk74	ams_wms0_491

2 Run the following command:

```
# lspv | grep -w rootvg
hdisk70 00c408c4dbd98818 rootvg active
hdisk72 00c408c4dbd98818 rootvg active
hdisk73 00c408c4dbd98818 rootvg active
hdisk74 00c408c4dbd98818 rootvg active
```

3 Remove the disk from DMP control.

```
# vxdisk rm ams wms0 491
```

4 Create the mksysb image. Use Network Installation Management (NIM) to install the operating system on the client, using the new image.

See the operating system documentation for detailed information about $\tt mksysb$ and NIM.

5 Verify the status after reinstalling the operating system, using the following command:

<pre># vxdmpadm native</pre>	list
PATH	DMPNODENAME
hdisk70	ams_wms0_491
hdisk72	ams_wms0_491
hdisk73	ams_wms0_491
hdisk74	ams_wms0_491

6 Verify the configuration.

# lspv	grep -w rootvg		
hdisk70	00c408c4dbd98818	rootvg	active
hdisk72	00c408c4dbd98818	rootvg	active
hdisk73	00c408c4dbd98818	rootvg	active
hdisk74	00c408c4dbd98818	rootvg	active
# lsvg -	p rootvg		
rootvg:			
PV_NAME	PV STATE TOTA	L PPs FRE	LE PPS FREE DISTRIBUTION
hdisk70	active 39	36	1270500101128

Upgrading Dynamic Multi-Pathing and AIX on a DMP-enabled rootvg

If the rootvg is enabled for DMP, refer to the *Storage Foundation Configuration and Upgrade Guide* for instructions on how to upgrade Dynamic Multi-Pathing, AIX, or both.

Using Storage Foundation in the logical partition (LPAR) with virtual SCSI devices

Storage Foundation provides support for virtual SCSI (vSCSI) devices on the VIO client. You can create and manage Veritas Volume Manager (VxVM) volumes on vSCSI devices, as on any other devices. Storage Foundation provides Dynamic Multi-Pathing (DMP) for vSCSI devices, by default. Storage Foundation can also co-exist with MPIO for multi-pathing. If you choose to use MPIO to multipath the vSCSI devices, DMP works in pass-through mode.

Use the vxddladm utility and the vxdmpadm utility to administer DMP for vSCSI devices. The vxddladm utility controls enabling and disabling DMP on vSCSI devices,

adding and removing supported arrays, and listing supported arrays. The vxdmpadm utility controls the I/O policy and the path policy for vSCSI devices.

Setting up DMP for vSCSI devices in the logical partition (LPAR)

DMP is enabled on LPARs by default. After you install or upgrade Storage Foundation in the LPAR, any vSCSI devices are under DMP control and MPIO is disabled.

If you have already installed or upgraded Storage Foundation in the Virtual I/O client, use the following procedure to enable DMP support for vSCSI devices. This procedure is only required if you have previously disabled DMP support for vSCSI devices.

To enable vSCSI support within DMP and disable MPIO

- 1 Enable vSCSI support.
 - # vxddladm enablevscsi
- **2** You are prompted to reboot the system, if required.

DMP takes control of the devices, for any array that has DMP support to use the array for vSCSI devices. You can add or remove DMP support for vSCSI for arrays.

See "Adding and removing DMP support for vSCSI devices for an array" on page 105.

About disabling DMP for vSCSI devices in the logical partition (LPAR)

DMP can co-exist with MPIO multi-pathing in the Virtual I/O client or logical partition (LPAR). To use MPIO for multi-pathing, you can override the default behavior which enables Dynamic Multi-Pathing (DMP) in the LPAR.

There are two ways to do this:

- Before you install or upgrade Storage Foundation in the Virtual I/O client See "Preparing to install or upgrade Storage Foundation with DMP disabled for vSCSI devices in the logical partition (LPAR)" on page 104.
- After Storage Foundation is installed in the Virtual I/O client See "Disabling DMP multi-pathing for vSCSI devices in the logical partition (LPAR) after installation or upgrade" on page 104.

Preparing to install or upgrade Storage Foundation with DMP disabled for vSCSI devices in the logical partition (LPAR)

Before you install or upgrade Storage Foundation, you can set an environment variable to disable DMP use for the vSCSI devices. Storage Foundation is installed with DMP in pass-through mode. MPIO is enabled for multi-pathing.

Note: When you upgrade an existing VxVM installation that has DMP enabled, then DMP remains enabled regardless of whether or not the environment variable __VXVM_DMP_VSCSI_ENABLE is set to no.

To disable DMP before installing or upgrading SF in the LPAR

- 1 Before you install or upgrade VxVM, set the environment variable _____VXVM_DMP_VSCSI_ENABLE to no.
 - # export ___VXVM_DMP_VSCSI_ENABLE=no

Note: The environment variable name ___VXVM_DMP_VSCSI_ENABLE begins with two underscore (_) characters.

2 Install Storage Foundation, as described in the *Veritas InfoScale Installation Guide*.

Disabling DMP multi-pathing for vSCSI devices in the logical partition (LPAR) after installation or upgrade

After VxVM is installed, use the vxddladm command to switch vSCSI devices between MPIO control and DMP control.

To return control to MPIO, disable vSCSI support with DMP. After DMP support has been disabled, MPIO takes control of the devices. MPIO implements multi-pathing features such as failover and load balancing; DMP acts in pass-through mode.

To disable vSCSI support within DMP and enable MPIO

- 1 Disable vSCSI support.
 - # vxddladm disablevscsi
- 2 You are prompted to reboot the system, if required.

Adding and removing DMP support for vSCSI devices for an array

Dynamic Multi-Pathing (DMP) controls the devices for any array that has DMP support to use the array for vSCSI devices.

To add or remove DMP support for an array for use with vSCSI devices

- 1 To determine if DMP support is enabled for an array, list all of the arrays that DMP supports for use with vSCSI devices:
 - # vxddladm listvscsi
- 2 If the support is not enabled, add support for using an array as a vSCSI device within DMP:

vxddladm addvscsi array_vid

3 If the support is enabled, you can remove the support so that the array is not used for vSCSI devices within DMP:

```
# vxddladm rmvscsi array_vid
```

4 You are prompted to reboot the system, if required.

How DMP handles I/O for vSCSI devices

On the VIO client, DMP uses the Active/Standby array mode for the vSCSI devices. Each path to the vSCSI device is through a VIO server. One VIO server is Active and the other VIO servers are Standby. An Active/Standby array permits I/O through a single Active path, and keeps the other paths on standby. During failover, I/O is scheduled on one of the standby paths. After failback, I/Os are scheduled back onto the original Active path.

The following command shows the vSCSI enclosure:

The following command shows the I/O policy for the vSCSI enclosure:

For vSCSI devices, DMP balances the load between the VIO servers, instead of balancing the I/O on paths. By default, the <code>iopolicy</code> attribute of the vSCSI array is set to <code>lunbalance</code>. When <code>lunbalance</code> is set, the vSCSI LUNs are distributed so that the I/O load is shared across the VIO servers. For example, if you have 10 LUNs and 2 VIO servers, 5 of them are configured so that VIO Server 1 is Active and VIO Server 2 is Standby. The other 5 are configured so that the VIO Server 2 is Active and VIO Server 1 is Standby. To turn off load sharing across VIO servers, set the <code>iopolicy</code> attribute to <code>nolunbalance</code>.

DMP dynamically balances the I/O load across LUNs. When you add or remove disks or paths in the VIO client, the load is rebalanced. Temporary failures like enabling or disabling paths or controllers do not cause the I/O load across LUNs to be rebalanced.

Setting the vSCSI I/O policy

By default, DMP balances the I/O load across VIO servers. This behavior sets the I/O policy attribute to lunbalance.

To display the current I/O policy attribute for the vSCSI array

• Display the current I/O policy for a vSCSI array:

To turn off the LUN balancing, set the I/O policy attribute for the vSCSI array to nolunbalance.

To set the I/O policy attribute for the vSCSI array

Set the I/O policy for a vSCSI array:

```
# vxdmpadm setattr vscsi iopolicy={lunbalance|nolunbalance}
```

Note: The DMP I/O policy for each vSCSI device is always Single-Active. You cannot change the DMP I/O policy for the vSCSI enclosure. Only one VIO server can be Active for each vSCSI device.

Administering DMP | 107
Running alt_disk_install, alt_disk_copy and related commands on the OS device when DMP native support
is enabled

Running alt_disk_install, alt_disk_copy and related commands on the OS device when DMP native support is enabled

When DMP is enabled for native OS devices, you can use the following procedures to run the alt_disk_install command, alt_disk_copy command, or related commands on the operating system device.

Running alt_disk_install in the physical environment

1 Find the DMP device corresponding to the OS device path on which you plan to run the alt disk install command.

vxdmpadm getdmpnode nodename=hdisk13
NAME STATE ENCLR-TYPE PATHS ENBL DSBL ENCLR-NAME
emc0_0039 ENABLED EMC 4 4 0 emc0

2 Close references to the associated subpaths. Run the following command on the DMP device:

vxdisk rm emc0_0039

3 Run the alt disk install command on the OS device.

Refer to the OS vendor documentation for the alt disk install command.

Running alt_disk_install in the VIOS environment

1 Find the DMP device corresponding to the OS device path on which you plan to run the alt_disk_install command.

vxdmpadm getdmpnode nodename=hdisk13
NAME STATE ENCLR-TYPE PATHS ENBL DSBL ENCLR-NAME
emc0_0039 ENABLED EMC 4 4 0 emc0

- 2 If the DMP device is exported to a VIO client, remove the mapping of the DMP device. From the VIOS, run the following command:
 - # /usr/ios/cli/ioscli rmvdev -vtd VTD_devicename

3 Close references to the associated subpaths. Run the following command on the DMP device:

vxdisk rm emc0_0039

4 Run the alt disk install command on the OS device.

Refer to the OS vendor documentation for the alt disk install command.

Administering DMP using the vxdmpadm utility

The vxdmpadm utility is a command-line administrative interface to Dynamic Multi-Pathing (DMP).

You can use the vxdmpadm utility to perform the following tasks:

- Retrieve the name of the DMP device corresponding to a particular path.
 See "Retrieving information about a DMP node" on page 109.
- Display consolidated information about the DMP nodes.
 See "Displaying consolidated information about the DMP nodes" on page 110.
- Display the members of a LUN group.
 See "Displaying the members of a LUN group" on page 112.
- List all paths under a DMP device node, HBA controller, enclosure, or array port.

See "Displaying paths controlled by a DMP node, controller, enclosure, or array port" on page 112.

- Display information about the HBA controllers on the host.
 See "Displaying information about controllers" on page 115.
- Display information about enclosures.
 See "Displaying information about enclosures" on page 116.
- Display information about array ports that are connected to the storage processors of enclosures.
 See "Displaying information about array ports" on page 116.
- Display information about devices that are controlled by third-party multi-pathing drivers.
 See "Displaying information about devices controlled by third-party drivers" on page 117.
- Display extended devices attributes.
 See "Displaying extended device attributes" on page 118.
- See "Suppressing or including devices from VxVM control" on page 121.

Suppress or include devices from DMP control.

- Gather I/O statistics for a DMP node, enclosure, path, or controller.
 See "Gathering and displaying I/O statistics" on page 121.
- Configure the attributes of the paths to an enclosure.
 See "Setting the attributes of the paths to an enclosure" on page 128.
- Display the redundancy level of a device or enclosure.
 See "Displaying the redundancy level of a device or enclosure" on page 129.
- Specify the minimum number of active paths.
 See "Specifying the minimum number of active paths" on page 130.
- Display or set the I/O policy that is used for the paths to an enclosure. See "Specifying the I/O policy" on page 131.
- Enable or disable I/O for a path, HBA controller or array port on the system.
 See "Disabling I/O for paths, controllers, array ports, or DMP nodes" on page 137.
- Rename an enclosure.
 See "Renaming an enclosure" on page 140.
- Configure how DMP responds to I/O request failures.
 See "Configuring the response to I/O failures" on page 140.
- Configure the I/O throttling mechanism.
 See "Configuring the I/O throttling mechanism" on page 142.
- Control the operation of the DMP path restoration thread.
 See "Configuring DMP path restoration policies" on page 145.
- Configure array policy modules.
 See "Configuring Array Policy Modules" on page 147.
- Get or set the values of various tunables used by DMP.
 See "DMP tunable parameters" on page 191.

See the vxdmpadm(1M) manual page.

Retrieving information about a DMP node

The following command displays the Dynamic Multi-Pathing (DMP) node that controls a particular physical path:

```
# vxdmpadm getdmpnode nodename=pathname
```

The physical path is specified by argument to the nodename attribute, which must be a valid path listed in the device directory.

The device directory is the /dev directory.

The command displays output similar to the following example output.

```
# vxdmpadm getdmpnode nodename=hdisk107
```

NAME STATE ENCLR-TYPE PATHS ENBL DSBL ENCLR-NAME emc_clariion0_17 ENABLED EMC_CLARiiON 8 8 0 emc_clariion0

Use the -v option to display the LUN serial number and the array volume ID.

```
# vxdmpadm -v getdmpnode nodename=hdisk107
```

NAME STATE ENCLR-TYPE PATHS ENBL DSBL ENCLR-NAME SERIAL-NO ARRAY_VOL_ID

emc_clariion0_17 ENABLED EMC_CLARiiON 8 8 0 emc_clariion0 600601601 17

Use the enclosure attribute with getdmpnode to obtain a list of all DMP nodes for the specified enclosure.

vxdmpadm getdmpnode enclosure=enc0

NAME	STATE	ENCLR-TYPE	PATHS	ENBL	DSBL	ENCLR-NAME
		==========				
hdisk11	ENABLED	ACME	2	2	0	enc0
hdisk12	ENABLED	ACME	2	2	0	enc0
hdisk13	ENABLED	ACME	2	2	0	enc0
hdisk14	ENABLED	ACME	2	2	0	enc0

Use the dmpnodename attribute with getdmpnode to display the DMP information for a given DMP node.

vxdmpadm getdmpnode dmpnodename=emc_clariion0_158

NAME	STATE	ENCLR-TYPE	PATHS	ENBL	DSBL	ENCLR-NAME
emc_clariion0_158	ENABLED	EMC_CLARIION	1	1	0	emc_clariion0

Displaying consolidated information about the DMP nodes

The vxdmpadm list dmpnode command displays the detail information of a Dynamic Multi-Pathing (DMP) node. The information includes the enclosure name, LUN serial number, port id information, device attributes, and so on.

The following command displays the consolidated information for all of the DMP nodes in the system:

vxdmpadm list dmpnode all

Use the enclosure attribute with list dmpnode to obtain a list of all DMP nodes for the specified enclosure.

vxdmpadm list dmpnode enclosure=enclosurename

For example, the following command displays the consolidated information for all of the DMP nodes in the enco enclosure.

vxdmpadm list dmpnode enclosure=enc0

Use the dmpnodename attribute with list dmpnode to display the DMP information for a given DMP node. The DMP node can be specified by name or by specifying a path name. The detailed information for the specified DMP node includes path information for each subpath of the listed DMP node.

The path state differentiates between a path that is disabled due to a failure and a path that has been manually disabled for administrative purposes. A path that has been manually disabled using the vxdmpadm disable command is listed as disabled (m).

vxdmpadm list dmpnode dmpnodename=dmpnodename

For example, the following command displays the consolidated information for the DMP node $emc_clariion0_{158}$.

vxdmpadm list dmpnode dmpnodename=emc_clariion0_158

dmpdev	= emc_clariion0_158
state	= enabled
enclosure	= emc_clariion0
cab-sno	= APM00042102192
asl	= libvxCLARiiON.so
vid	= DGC
pid	= CLARiiON
array-name	= EMC_CLARIION
array-type	= CLR-A/P
iopolicy	= MinimumQ
avid	= -
lun-sno	= 6006016070071100F6BF98A778EDD811
udid	= DGC%5FCLARiiON%5FAPM00042102192%5F6006016070071100F6BF98A778EDD811
dev-attr	= -
###path	= name state type transport ctlr hwpath aportID aportWWN attr
path	= hdisk11 enabled(a) primary FC fscsi0 07-08-02 B0APM00042102192
50:06:01:68	:10:21:26:c1 -
path	= hdisk31 disabled secondary FC fscsi1 08-08-02 A0APM00042102192
50:06:01:60	:10:21:26:c1 -

Displaying the members of a LUN group

The following command displays the Dynamic Multi-Pathing (DMP) nodes that are in the same LUN group as a specified DMP node:

vxdmpadm getlungroup dmpnodename=dmpnode

For example:

```
# vxdmpadm getlungroup dmpnodename=hdisk16
```

NAME	STATE	ENCLR-TYPE	PATHS	ENBL	DSBL	ENCLR-NAME
hdisk14	ENABLED	ACME	2	2	0	enc1
hdisk15	ENABLED	ACME	2	2	0	encl
hdisk16	ENABLED	ACME	2	2	0	encl
hdisk17	ENABLED	ACME	2	2	0	enc1

Displaying paths controlled by a DMP node, controller, enclosure, or array port

The vxdmpadm getsubpaths command lists all of the paths known to Dynamic Multi-Pathing (DMP). The vxdmpadm getsubpaths command also provides options to list the subpaths through a particular DMP node, controller, enclosure, or array port. To list the paths through an array port, specify either a combination of enclosure name and array port id, or array port worldwide name (WWN).

To list all subpaths known to DMP:

vxdmpadm getsubpaths

NAME	STATE [A]	PATH-TYPE[M]	DMPNODENAME	ENCLR-NAME	CTLR	ATTRS	
hdisk1	ENABLED(A)	-	disk_0	disk	scsi0	-	
hdisk0	ENABLED(A)	-	disk_1	disk	scsi0	-	
hdisk107	ENABLED(A)	PRIMARY	emc_clariion	0_17 emc_clar	iion0 f	scsil	-
hdisk17	ENABLED	SECONDARY	emc_clariion	0_17 emc_clar	iion0 f	scsi0	-
hdisk108	ENABLED(A)	PRIMARY	emc_clariion	0_74 emc_clar	iion0 f	scsil	-
hdisk18	ENABLED	SECONDARY	emc_clariion	0_74 emc_clar	iion0 f	scsi0	-
hdisk109	ENABLED(A)	PRIMARY	emc_clariion	0_75 emc_clar	iion0 f	scsil	-
hdisk19	ENABLED	SECONDARY	emc_clariion	0_75 emc_clar	iion0 f	scsi0	-

The vxdmpadm getsubpaths command combined with the dmpnodename attribute displays all the paths to a LUN that are controlled by the specified DMP node name from the /dev/vx/rdmp directory:

vxdmpadm getsubpaths dmpnodename=hdisk22

NAME	STATE [A]	PATH-TYPE[M]	CTLR-NAME	ENCLR-TYPE	ENCLR-NAME	ATTRS
hdisk22	ENABLED(A)	PRIMARY	scsi2	ACME	enc0	-
hdisk21	ENABLED	PRIMARY	scsil	ACME	enc0	-

For A/A arrays, all enabled paths that are available for I/O are shown as ENABLED (A).

For A/P arrays in which the I/O policy is set to singleactive, only one path is shown as ENABLED(A). The other paths are enabled but not available for I/O. If the I/O policy is not set to singleactive, DMP can use a group of paths (all primary or all secondary) for I/O, which are shown as ENABLED(A).

See "Specifying the I/O policy" on page 131.

Paths that are in the DISABLED state are not available for I/O operations.

A path that was manually disabled by the system administrator displays as DISABLED(M). A path that failed displays as DISABLED.

You can use getsubpaths to obtain information about all the paths that are connected to a particular HBA controller:

vxdmpadm getsubpaths ctlr=fscsi1

1102201102	21112222	020011011111	
hdisk108	ENABLED(A)	PRIMARY	<pre>emc_clariion0_74 EMC_CLARiiON emc_clariion0 -</pre>
hdisk63	ENABED	SECONDARY	<pre>emc_clariion0_74 EMC_CLARiiON emc_clariion0 -</pre>

You can also use getsubpaths to obtain information about all the paths that are connected to a port on an array. The array port can be specified by the name of the enclosure and the array port ID, or by the WWN identifier of the array port:

- # vxdmpadm getsubpaths enclosure=enclosure portid=portid
- # vxdmpadm getsubpaths pwwn=pwwn

For example, to list subpaths through an array port through the enclosure and the array port ID:

vxdmpadm getsubpaths enclosure=emc_clariion0 portid=A2

NAME	STATE [A]	PATH-TYPE[M]	DMPI	NODENAME	ENCI	LR-NA	AME CTI	R	ATTI	٢S
								====		
hdisk111	ENABLED(A)	PRIMARY	emc	_clariion0	_80	emc	clariion	0 fs	scsil	-

```
hdisk51ENABLED(A)PRIMARYemc_clariion0_80emc_clariion0 fscsi0 -hdisk112ENABLED(A)PRIMARYemc_clariion0_81emc_clariion0 fscsi1 -hdisk52ENABLED(A)PRIMARYemc_clariion0_81emc_clariion0 fscsi0 -
```

For example, to list subpaths through an array port through the WWN:

NAME	STATE [A]	PATH-TYPE[M]	DMPNODENAME	ENCLR-NAME	CTLR	ATTRS	
=======							
hdisk111	ENABLED(A)	PRIMARY	emc_clariion	0_80 emc_cla	riion0	fscsil -	
hdisk51	ENABLED(A)	PRIMARY	emc_clariion	0_80 emc_cla	riion0	fscsi0 -	
hdisk112	ENABLED(A)	PRIMARY	emc_clariion	0_81 emc_cla	riion0	fscsil -	
hdisk52	ENABLED(A)	PRIMARY	emc_clariion	0_81 emc_clar	riion0	fscsi0 -	

You can use getsubpaths to obtain information about all the subpaths of an enclosure.

```
# vxdmpadm getsubpaths enclosure=enclosure name [ctlr=ctlrname]
```

To list all subpaths of an enclosure:

vxdmpadm getsubpaths enclosure=emc_clariion0

NAME STAT	TE[A] PATH-TYPE[M]	DMPNODENAME	ENCLR-NAME	CTLR A	ATTRS
hdisk107 ENAM	BLED(A) PRIMARY	emc_clariion0	_17 emc_clar	iion0 fscs	sil -
hdisk17 ENAM	BLED SECONDARY	emc_clariion0	_17 emc_clar	iion0 fscs	3i0 -
hdisk110 ENAM	BLED(A) PRIMARY	emc_clariion0	_76 emc_clar	iion0 fscs	sil -
hdisk20 ENAM	BLED SECONDARY	emc_clariion0	_76 emc_clar	iion0 fscs	3i0 -

To list all subpaths of a controller on an enclosure:

By default, the output of the vxdmpadm getsubpaths command is sorted by enclosure name, DMP node name, and within that, path name.

To sort the output based on the pathname, the DMP node name, the enclosure name, or the host controller name, use the -s option.

To sort subpaths information, use the following command:

```
# vxdmpadm -s {path | dmpnode | enclosure | ctlr} getsubpaths \
[all | ctlr=ctlr_name | dmpnodename=dmp_device_name | \
enclosure=enclr_name [ctlr=ctlr_name | portid=array_port_ID] | \
pwwn=port WWN | tpdnodename=tpd node name]
```

See "Setting customized names for DMP nodes" on page 73.

Displaying information about controllers

The following Dynamic Multi-Pathing (DMP) command lists attributes of all HBA controllers on the system:

vxdmpadm listctlr all

CTLR-NAME	ENCLR-TYPE	STATE	ENCLR-NAME	PATH_COUNT
scsil	OTHER	ENABLED	other0	3
scsi2	X1	ENABLED	jbod0	10
scsi3	ACME	ENABLED	enc0	24
scsi4	ACME	ENABLED	enc0	24

This output shows that the controller scsil is connected to disks that are not in any recognized DMP category as the enclosure type is OTHER.

The other controllers are connected to disks that are in recognized DMP categories.

All the controllers are in the ENABLED state, which indicates that they are available for I/O operations.

The state DISABLED is used to indicate that controllers are unavailable for I/O operations. The unavailability can be due to a hardware failure or due to I/O operations being disabled on that controller by using the vxdmpadm disable command.

The following forms of the command lists controllers belonging to a specified enclosure or enclosure type:

vxdmpadm listctlr enclosure=enc0

or

vxdmpadm listctlr type=ACME

CTLR-NAME	ENCLR-TYPE	STATE	ENCLR-NAME	PATH_COUNT
scsi2	ACME	ENABLED	enc0	10
scsi3	ACME	ENABLED	enc0	24

The vxdmpadm getctlr command displays HBA vendor details and the Controller ID. For iSCSI devices, the Controller ID is the IQN or IEEE-format based name. For FC devices, the Controller ID is the WWN. Because the WWN is obtained from ESD, this field is blank if ESD is not running. ESD is a daemon process used to notify DDL about occurrence of events. The WWN shown as 'Controller ID' maps to the WWN of the HBA port associated with the host controller.

Displaying information about enclosures

- -

Dynamic Multi-Pathing (DMP) can display the attributes of the enclosures, including the enclosure type, enclosure serial number, status, array type, number of LUNs, and the firmware version, if available.

To display the attributes of a specified enclosure, use the following DMP command:

# vxdmpadm	listenclosu	ire emc0				
ENCLR_NAME	ENCLR_TYPE	ENCLR_SNO	STATUS	ARRAY_TYPE	LUN_COUNT	FIRMWARE
emc0	EMC	000292601383	CONNECTED	A/A	30	5875

To display the attrtibutes for all enclosures in a system, use the following DMP command:

vxdmpadm listenclosure all

ENCLR_NAME	ENCLR_TYPE	ENCLR_SNO	STATUS	ARRAY_TYPE	LUN_COUNT	FIRMWARE
Disk	Disk	DISKS	CONNECTED	Disk	6	-
emc0	EMC	000292601383	CONNECTED	A/A	1	5875
hitachi_usp-vm0	Hitachi_USP-VM	25847	CONNECTED	A/A	1	6008
emc_clariion0	EMC_CLARiiON	CK20007040035	CONNECTED	CLR-A/PF	2	0324

If an A/P or ALUA array is under the control of MPIO, then DMP claims the devices in A/A mode. The output of the above commands shows the ARRAY_TYPE as A/A. For arrays under MPIO control, DMP does not store A/P-specific attributes or ALUA-specific attributes. These attributes include primary/secondary paths, port serial number, and the array controller ID.

Displaying information about array ports

Use the Dynamic Multi-Pathing (DMP) commands in this section to display information about array ports. The information displayed for an array port includes the name of its enclosure, its ID, and its worldwide name (WWN) identifier.

Note: DMP does not report information about array ports for LUNs that are controlled by the native multi-pathing driver. DMP reports pWWN information only if the dmp_monitor_fabric tunable is on, and the event source daemon (esd) is running.

To display the attributes of an array port that is accessible through a path, DMP node or HBA controller, use one of the following commands:

```
# vxdmpadm getportids path=path_name
```

- # vxdmpadm getportids dmpnodename=dmpnode_name
- # vxdmpadm getportids ctlr=ctlr_name

The following form of the command displays information about all of the array ports within the specified enclosure:

vxdmpadm getportids enclosure=enclr_name

The following example shows information about the array port that is accessible through DMP node hdisk12:

```
# vxdmpadm getportids dmpnodename=hdisk12
```

NAME	ENCLR-NAME	ARRAY-PORT-ID	PWWN
hdisk12	HDS9500V0	1A	20:00:00:E0:8B:06:5F:19

Displaying information about devices controlled by third-party drivers

The third-party driver (TPD) coexistence feature allows I/O that is controlled by third-party multi-pathing drivers to bypass Dynamic Multi-Pathing (DMP) while retaining the monitoring capabilities of DMP. The following commands allow you to display the paths that DMP has discovered for a given TPD device, and the TPD device that corresponds to a given TPD-controlled node discovered by DMP:

vxdmpadm getsubpaths tpdnodename=TPD_node_name

```
# vxdmpadm gettpdnode nodename=TPD_path_name
```

See "Changing device naming for enclosures controlled by third-party drivers" on page 169.

For example, consider the following disks in an EMC Symmetrix array controlled by PowerPath, which are known to DMP:

vxdisk list

DEVICE	TYPE	DISK	GROUP	STATUS
hdiskpower10	auto:cdsdisk	disk1	ppdg	online

hdiskpower11	auto:cdsdisk	disk2	ppdg	online
hdiskpower12	auto:cdsdisk	disk3	ppdg	online
hdiskpower13	auto:cdsdisk	disk4	ppdg	online
hdiskpower14	auto:cdsdisk	disk5	ppdg	online
hdiskpower15	auto:cdsdisk	disk6	ppdg	online
hdiskpower16	auto:cdsdisk	disk7	ppdg	online
hdiskpower17	auto:cdsdisk	disk8	ppdg	online
hdiskpower18	auto:cdsdisk	disk9	ppdg	online
hdiskpower19	auto:cdsdisk	disk10	ppdg	online

The following command displays the paths that DMP has discovered, and which correspond to the PowerPath-controlled node, emcpower10:

vxdmpadm getsubpaths tpdnodename=hdiskpower10

NAME	TPDNODENAME	PATH-TYPE [-] DM	MP-NODENAME	ENCLR-TYPE	ENCLR-NAME
hdisk10	hdiskpower10s	s2 -	hdiskpower1) EMC	EMC0
hdisk20	hdiskpower10s	s2 -	hdiskpower1) EMC	EMC0

Conversely, the next command displays information about the PowerPath node that corresponds to the path, hdisk10, discovered by DMP:

vxdmpadm gettpdnode nodename=hdiskpower10

NAME	STATE	PATHS	ENCLR-TYPE	ENCLR-NAME
hdiskpower10	s2 ENABLE	D 2	EMC	EMC0

Displaying extended device attributes

Device Discovery Layer (DDL) extended attributes are attributes or flags corresponding to a Veritas Volume Manager (VxVM) or Dynamic Multi-Pathing (DMP) LUN or disk and that are discovered by DDL. These attributes identify a LUN to a specific hardware category.

Table 4-1 describes the list of categories.

 Table 4-1
 Categories for extended attributes

Category	Description
Hardware RAID types	Displays what kind of Storage RAID Group the LUN belongs to

Category	Description
Thin Provisioning Discovery and Reclamation	Displays the LUN's thin reclamation abilities
Device Media Type	Displays the type of media –whether SSD (solid state disk)
Storage-based Snapshot/Clone	Displays whether the LUN is a SNAPSHOT or a CLONE of a PRIMARY LUN
Storage-based replication	Displays if the LUN is part of a replicated group across a remote site
Transport	Displays what kind of HBA is used to connect to this LUN (FC, SATA, iSCSI)

 Table 4-1
 Categories for extended attributes (continued)

Each LUN can have one or more of these extended attributes. DDL discovers the extended attributes during device discovery from the Array Support Library (ASL). If Veritas Operations Manager (VOM) is present, DDL can also obtain extended attributes from the VOM Management Server for hosts that are configured as managed hosts.

The vxdisk -p list command displays DDL extended attributes. For example, the following command shows attributes of std, fc, and RAID 5 for this LUN:

vxdisk -p list

DISK	:	tagmastore-usp0_0e18
DISKID	:	1253585985.692.rx2600h11
VID	:	HITACHI
UDID	:	HITACHI%5FOPEN-V%5F02742%5F0E18
REVISION	:	5001
PID	:	OPEN-V
PHYS_CTLR_NAME	:	0/4/1/1.0x50060e8005274246
LUN_SNO_ORDER	:	411
LUN_SERIAL_NO	:	0E18
LIBNAME	:	libvxhdsusp.sl
HARDWARE_MIRROR	:	no
DMP_DEVICE	:	tagmastore-usp0_0e18
DDL_THIN_DISK	:	thick
DDL_DEVICE_ATTR	:	std fc RAID_5
CAB_SERIAL_NO	:	02742
ATYPE	:	A/A
ARRAY_VOLUME_ID	:	0E18

```
ARRAY_PORT_PWWN: 50:06:0e:80:05:27:42:46
ANAME : TagmaStore-USP
TRANSPORT : FC
```

The vxdisk -x attribute -p list command displays the one-line listing for the property list and the attributes. The following example shows two Hitachi LUNs that support Thin Reclamation through the attribute hdprclm:

```
# vxdisk -x DDL_DEVICE_ATTR -p list
DEVICE DDL_DEVICE_ATTR
tagmastore-usp0_0a7a std fc RAID_5
tagmastore-usp0_065a hdprclm fc
tagmastore-usp0_065b hdprclm fc
```

User can specify multiple -x options in the same command to display multiple entries. For example:

```
# vxdisk -x DDL_DEVICE_ATTR -x VID -p list
```

DEVICE	DDL_DEVICE_ATTR	VID
tagmastore-usp0_0a7a	std fc RAID_5	HITACHI
tagmastore-usp0_0a7b	std fc RAID_5	HITACHI
tagmastore-usp0_0a78	std fc RAID_5	HITACHI
tagmastore-usp0_0a79	std fc RAID_5	HITACHI
tagmastore-usp0_065a	hdprclm fc	HITACHI
tagmastore-usp0_065b	hdprclm fc	HITACHI
tagmastore-usp0_065c	hdprclm fc	HITACHI
tagmastore-usp0_065d	hdprclm fc	HITACHI

Use the vxdisk -e list command to show the DLL_DEVICE_ATTR property in the last column named ATTR.

```
# vxdisk -e list
```

DEVICE	TYPE	DISK	GROUP	STATUS	OS_NATIVE_NAME	ATTR
tagmastore-usp0_0a7a	auto	-	-	online	c10t0d2	std fc RAID_5
tagmastore-usp0_0a7b	auto	-	-	online	c10t0d3	std fc RAID_5
tagmastore-usp0_0a78	auto	-	-	online	c10t0d0	std fc RAID_5
tagmastore-usp0_0655	auto	-	-	online	c13t2d7	hdprclm fc
tagmastore-usp0_0656	auto	-	-	online	c13t3d0	hdprclm fc
tagmastore-usp0_0657	auto	-	-	online	c13t3d1	hdprclm fc

For a list of ASLs that supports Extended Attributes, and descriptions of these attributes, refer to the hardware compatibility list (HCL) at the following URL:

http://www.symantec.com/docs/TECH211575

Note: DMP does not support Extended Attributes for LUNs that are controlled by the native multi-pathing driver.

Suppressing or including devices from VxVM control

The vxdmpadm exclude command suppresses devices from Veritas Volume Manager (VxVM) based on the criteria that you specify. When a device is suppressed, Dynamic Multi-Pathing (DMP) does not claim the device so that the device is not available for VxVM to use. You can add the devices back into VxVM control with the vxdmpadm include command. The devices can be included or excluded based on VID:PID combination, paths, controllers, or disks. You can use the bang symbol (!) to exclude or include any paths or controllers except the one specified.

The root disk cannot be suppressed. The operation fails if the VID:PID of an external disk is the same VID:PID as the root disk and the root disk is under DMP rootability control.

Note: The ! character is a special character in some shells. The following syntax shows how to escape it in a bash shell.

```
# vxdmpadm exclude { all | product=VID:PID |
ctlr=[\!]ctlrname | dmpnodename=diskname [ path=[\!]pathname] }
# vxdmpadm include { all | product=VID:PID |
ctlr=[\!]ctlrname | dmpnodename=diskname [ path=[\!]pathname] }
where:
```

all	all devices
product=VID:PID	all devices with the specified VID:PID
ctlr= <i>ctlrname</i>	all devices through the given controller
dmpnodename=diskname	all paths under the DMP node
dmpnodename=diskname path=\!pathname	all paths under the DMP node except the one specified

Gathering and displaying I/O statistics

You can use the vxdmpadm iostat command to gather and display I/O statistics for a specified DMP node, enclosure, path, port, or controller.

The statistics displayed are the CPU usage and amount of memory per CPU used to accumulate statistics, the number of read and write operations, the number of kilobytes read and written, and the average time in milliseconds per kilobyte that is read or written.

To enable the gathering of statistics, enter this command:

```
# vxdmpadm iostat start [memory=size]
```

The memory attribute limits the maximum amount of memory that is used to record I/O statistics for each CPU. The default limit is 32k (32 kilobytes) per CPU.

To reset the I/O counters to zero, use this command:

```
# vxdmpadm iostat reset
```

To display the accumulated statistics at regular intervals, use the following command:

```
# vxdmpadm iostat show {filter} [interval=seconds [count=N]]
```

The above command displays I/O statistics for the devices specified by the *filter*. The *filter* is one of the following:

- ∎ all
- ctlr=ctlr-name
- dmpnodename=dmp-node
- enclosure=enclr-name [portid=array-portid] [ctlr=ctlr-name]
- pathname=path-name
- pwwn=array-port-wwn [ctlr=ctlr-name]

Use the interval and count attributes to specify the interval in seconds between displaying the I/O statistics, and the number of lines to be displayed. The actual interval may be smaller than the value specified if insufficient memory is available to record the statistics.

DMP also provides a *groupby* option to display cumulative I/O statistics, aggregated by the specified criteria.

See "Displaying cumulative I/O statistics" on page 123.

To disable the gathering of statistics, enter this command:

```
# vxdmpadm iostat stop
```

Displaying cumulative I/O statistics

The vxdmpadm iostat command provides the ability to analyze the I/O load distribution across various I/O channels or parts of I/O channels. Select the appropriate *filter* to display the I/O statistics for the DMP node, controller, array enclosure, path, port, or virtual machine. Then, use the *groupby* clause to display cumulative statistics according to the criteria that you want to analyze. If the groupby clause is not specified, then the statistics are displayed per path.

When you combine the *filter* and the *groupby* clause, you can analyze the I/O load for the required use case scenario. For example:

- To compare I/O load across HBAs, enclosures, or array ports, use the groupby clause with the specified attribute.
- To analyze I/O load across a given I/O channel (HBA to array port link), use filter by HBA and PWWN or enclosure and array port.
- To analyze I/O load distribution across links to an HBA, use *filter* by HBA and groupby array port.

Use the following format of the iostat command to analyze the I/O loads:

```
# vxdmpadm [-u unit] iostat show [groupby=criteria] {filter} \
[interval=seconds [count=N]]
```

The above command displays I/O statistics for the devices specified by the *filter*. The *filter* is one of the following:

- all
- ctlr=ctlr-name
- dmpnodename=dmp-node
- enclosure=enclr-name [portid=array-portid] [ctlr=ctlr-name]
- pathname=path-name
- pwwn=array-port-wwn[ctlr=ctlr-name]

You can aggregate the statistics by the following groupby criteria:

- arrayport
- ctlr
- dmpnode
- enclosure

By default, the read/write times are displayed in milliseconds up to 2 decimal places. The throughput data is displayed in terms of BLOCKS, and the output is scaled, meaning that the small values are displayed in small units and the larger values are displayed in bigger units, keeping significant digits constant. You can specify the units in which the statistics data is displayed. The -u option accepts the following options:

h or H	Displays throughput in the highest possible unit.
k	Displays throughput in kilobytes.
m	Displays throughput in megabytes.
g	Displays throughput in gigabytes.
bytes b	Displays throughput in exact number of bytes.
us	Displays average read/write time in microseconds.

To group by DMP node:

vxdmpadm [-u unit] iostat show groupby=dmpnode \
[all | dmpnodename=dmpnodename | enclosure=enclr-name]

To group by controller:

```
# vxdmpadm [-u unit] iostat show groupby=ctlr [ all | ctlr=ctlr ]
```

For example:

vxdmpadm iostat show groupby=ctlr ctlr=fscsi0

cpu usage	= 843us	per	cpu memo	ry = 4915	2b	
	OPE	RATIONS	BLO	CKS	AVG	TIME(ms)
CTLRNAME	READS	WRITES	READS	WRITES	READS	WRITES
fscsi0	276	0	2205	0	0.03	0.00

To group by arrayport:

```
# vxdmpadm [-u unit] iostat show groupby=arrayport [ all \
    pwwn=array_pwwn | enclosure=enclr portid=array-port-id ]
```

For example:

vxdmpadm -u m iostat show groupby=arrayport \
enclosure=HDS9500-ALUA0 portid=1A

	OPERATIONS		BYTES		AVG TIME(ms)	
PORTNAME	READS	WRITES	READS	WRITES	READS	WRITES
1A	743	1538	11m	24m	17.13	8.61

To group by enclosure:

```
# vxdmpadm [-u unit] iostat show groupby=enclosure [ all \
    enclosure=enclr ]
```

For example:

```
# vxdmpadm -u h iostat show groupby=enclosure enclosure=EMC CLARiiON0
```

OPERATIONSBLOCKSAVG TIME (ms)ENCLOSURENAMEREADSWRITESREADSWRITESEMC CLARIIONO743153811392k24176k17.138.61

You can also filter out entities for which all data entries are zero. This option is especially useful in a cluster environment that contains many failover devices. You can display only the statistics for the active paths.

To filter all zero entries from the output of the iostat show command:

```
# vxdmpadm [-u unit] -z iostat show [all|ctlr=ctlr_name |
dmpnodename=dmp_device_name | enclosure=enclr_name [portid=portid] |
pathname=path_name|pwwn=port_WWN][interval=seconds [count=N]]
```

For example:

vxdmpadm -z iostat show dmpnodename=hdisk40

cpu usage	= 906u	s per	cpu memo	ory = 491	52b	
	OPE	RATIONS	BLOO	CKS	AVG	TIME(ms)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk100	7	0	70	0	0.02	0.00
hdisk115	12	0	58	0	0.03	0.00
hdisk40	10	0	101	0	0.02	0.00
hdisk55	5	0	21	0	0.04	0.00

To display average read/write times in microseconds.

vxdmpadm -u us iostat show pathname=hdisk115

cpu usage	= 1030us	per c	pu memor	y = 49152b		
	OPERA	TIONS	BLOC	CKS	AVG	TIME(us)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk115	12	0	58	0	32.00	0.00

Displaying statistics for queued or erroneous I/Os

Use the vxdmpadm iostat show command with the -q option to display the I/Os queued in Dynamic Multi-Pathing (DMP) for a specified DMP node, or for a specified

path or controller. For a DMP node, the -q option displays the I/Os on the specified DMP node that were sent to underlying layers. If a path or controller is specified, the -q option displays I/Os that were sent to the given path or controller and not yet returned to DMP.

See the vxdmpadm(1m) manual page for more information about the vxdmpadm iostat command.

To display queued I/O counts on a DMP node:

```
# vxdmpadm -q iostat show [filter] [interval=n [count=m]]
```

For example:

<pre># vxdmpadm -q iostat</pre>	show dmpr	nodename=ho	disk10	
cpu usage = 529us	per cpu n	nemory = 49	9152b	
	QUEUEI	D I/Os	PENDING	I/Os
DMPNODENAME	READS	WRITES		
hdisk10	0	0	0	

To display the count of I/Os that returned with errors on a DMP node, path, or controller:

```
# vxdmpadm -e iostat show [filter] [interval=n [count=m]]
```

For example, to show the I/O counts that returned errors on a path:

```
# vxdmpadm -e iostat show pathname=hdisk55
```

cpu usage = 656us	per cpu	memory =	49152b			
ERROR I/Os						
PATHNAME	READS	WRITES				
hdisk55	0	0				

Examples of using the vxdmpadm iostat command

Dynamic Multi-Pathing (DMP) enables you to gather and display I/O statistics with the vxdmpadm iostat command. This section provides an example session using the vxdmpadm iostat command.

The first command enables the gathering of I/O statistics:

```
# vxdmpadm iostat start
```

The next command displays the current statistics including the accumulated total numbers of read and write operations, and the kilobytes read and written, on all paths.

		cpu usage	= 7952us	per cpu	memory =	8192b
	OPEF	ATIONS	BYTES	5	AVG TI	ME(ms)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk10	87	0	44544k	0	0.00	0.00
hdisk16	0	0	0	0	0.00	0.00
hdisk11	87	0	44544k	0	0.00	0.00
hdisk17	0	0	0	0	0.00	0.00
hdisk12	87	0	44544k	0	0.00	0.00
hdisk18	0	0	0	0	0.00	0.00
hdisk13	87	0	44544k	0	0.00	0.00
hdisk19	0	0	0	0	0.00	0.00
hdisk14	87	0	44544k	0	0.00	0.00
hdisk20	0	0	0	0	0.00	0.00
hdisk15	87	0	44544k	0	0.00	0.00
hdisk21	0	0	0	0	0.00	0.00

vxdmpadm -u k iostat show all

The following command changes the amount of memory that vxdmpadm can use to accumulate the statistics:

vxdmpadm iostat start memory=4096

The displayed statistics can be filtered by path name, DMP node name, and enclosure name (note that the per-CPU memory has changed following the previous command):

# vxdmpadm -u k iostat show pathname=hdisk17							
		cpu usage	= 8132us	per cpu	memory =	4096b	
	OPEF	RATIONS	BYT	ES	AVG T	IME(ms)	
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES	
hdisk17	0	0	0	0	0.00	0.00	

vxdmpadm -u k iostat show dmpnodename=hdisk10

		cpu usage	= 8501us	per cpu	memory =	4096b
	OPE	RATIONS	B	YTES	AVG	TIME(ms)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk10	1088	0	557056k	0	0.00	0.00

vxdmpadm -u k iostat show enclosure=Disk

		cpu usage	= 8626us	per cpu	memory =	4096b
	OPE	RATIONS	BYTES	3	AVG TI	IME (ms)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk10	1088	0	557056k	0	0.00	0.00

You can also specify the number of times to display the statistics and the time interval. Here the incremental statistics for a path are displayed twice with a 2-second interval:

vxdmpadm iostat show pathname=hdisk17 interval=2 count=2

		cpu usa		s per cj	pu memory	= 49152b
	OPE	RATIONS	В	LOCKS	AVG T	IME(ms)
PATHNAME	READS	WRITES	READS	WRITES	READS	WRITES
hdisk17	0	0	0	0	0.00	0.00
hdisk17	0	0	0	0	0.00	0.00

Setting the attributes of the paths to an enclosure

You can use the wxdmpadm setattr command to set the attributes of the paths to an enclosure or disk array.

The attributes set for the paths are persistent across reboots or product upgrades.

You can set the following attributes:

active	Changes a standby (failover) path to an active path. The following example specifies an active path for an array:						
	<pre># vxdmpadm setattr path hdisk10 pathtype=active</pre>						
nomanual	Restores the original primary or secondary attributes of a path. This example restores the path to a JBOD disk:						
	<pre># vxdmpadm setattr path hdisk20 pathtype=nomanual</pre>						
nopreferred	Restores the normal priority of a path. The following example restores the default priority to a path:						
	<pre># vxdmpadm setattr path hdisk16 pathtype=nopreferred</pre>						

preferred [priority=N]	Specifies a path as preferred, and optionally assigns a priority number to it. If specified, the priority number must be an integer that is greater than or equal to one. Higher priority numbers indicate that a path is able to carry a greater I/O load.					
	Note: Setting a priority for path does not change the I/O policy. The I/O policy must be set independently.					
	See "Specifying the I/O policy" on page 131.					
	This example first sets the I/O policy to priority for an Active/Active disk array, and then specifies a preferred path with an assigned priority of 2:					
	# vxdmpadm setattr enclosure enc0 $\$					
	<pre>iopolicy=priority # vxdmpadm setattr path hdisk16 pathtype=preferred \ priority=2</pre>					
primary	Defines a path as being the primary path for a JBOD disk array. The following example specifies a primary path for a JBOD disk array:					
	<pre># vxdmpadm setattr path hdisk20 pathtype=primary</pre>					
secondary	Defines a path as being the secondary path for a JBOD disk array. The following example specifies a secondary path for a JBOD disk array:					
	<pre># vxdmpadm setattr path hdisk22 \ pathtype=secondary</pre>					
standby	Marks a standby (failover) path that it is not used for normal I/O scheduling. This path is used if there are no active paths available for I/O. The next example specifies a standby path for an A/P-C disk array:					
	<pre># vxdmpadm setattr path hdisk10 \ pathtype=standby</pre>					

Displaying the redundancy level of a device or enclosure

Use the $\mathtt{vxdmpadm}$ getdmpnode command to list the devices with less than the required redundancy level.

To list the devices on a specified enclosure with fewer than a given number of enabled paths, use the following command:

vxdmpadm getdmpnode enclosure=encl_name redundancy=value

For example, to list the devices with fewer than 3 enabled paths, use the following command:

vxdmpadm getdmpnode enclosure=EMC CLARiiON0 redundancy=3

NAME	STATE	ENCLR-TYPE	PATHS	ENBL	DSBL	ENCLR-NAME
emc_clariion0_162	ENABLED	EMC_CLARiiON	3	2	1	emc_clariion0
emc_clariion0_182	ENABLED	EMC_CLARiiON	2	2	0	emc_clariion0
emc_clariion0_184	ENABLED	EMC_CLARiiON	3	2	1	emc_clariion0
emc_clariion0_186	ENABLED	EMC_CLARiiON	2	2	0	emc_clariion0

To display the minimum redundancy level for a particular device, use the vxdmpadm getattr command, as follows:

```
# vxdmpadm getattr enclosure|arrayname|arraytype \
    component-name redundancy
```

For example, to show the minimum redundancy level for the enclosure HDS9500-ALUA0:

vxdmpadm getattr enclosure HDS9500-ALUA0 redundancy

ENCLR_NAME DEFAULT CURRENT HDS9500-ALUA0 0 4

Specifying the minimum number of active paths

You can set the minimum redundancy level for a device or an enclosure. The minimum redundancy level is the minimum number of paths that should be active for the device or the enclosure. If the number of paths falls below the minimum redundancy level for the enclosure, a message is sent to the system console and also logged to the Dynamic Multi-Pathing (DMP) log file. Also, notification is sent to vxnotify clients.

The value set for minimum redundancy level is persistent across reboots and product upgrades. If no minimum redundancy level is set, the default value is 0.

You can use the ${\tt vxdmpadm}$ setattr command to set the minimum redundancy level.

To specify the minimum number of active paths

Use the vxdmpadm setattr command with the redundancy attribute as follows:

vxdmpadm setattr enclosure|arrayname|arraytype component-name redundancy=value

where value is the number of active paths.

For example, to set the minimum redundancy level for the enclosure HDS9500-ALUA0:

```
# vxdmpadm setattr enclosure HDS9500-ALUA0 redundancy=2
```

Displaying the I/O policy

To display the current and default settings of the I/O policy for an enclosure, array, or array type, use the vxdmpadm getattr command.

The following example displays the default and current setting of iopolicy for JBOD disks:

vxdmpadm getattr enclosure Disk iopolicy

ENCLR_NAME	DEFAULT	CURRENT
Disk	MinimumQ	Balanced

The next example displays the setting of partitionsize for the enclosure enco, on which the balanced I/O policy with a partition size of 2MB has been set:

vxdmpadm getattr enclosure enc0 partitionsize

ENCLR_NAME	DEFAULT	CURRENT
enc0	2048	4096

Specifying the I/O policy

You can use the vxdmpadm setattr command to change the Dynamic Multi-Pathing (DMP) I/O policy for distributing I/O load across multiple paths to a disk array or enclosure. You can set policies for an enclosure (for example, HDS01), for all enclosures of a particular type (such as HDS), or for all enclosures of a particular array type (such as A/A for Active/Active, or A/P for Active/Passive).

Note: I/O policies are persistent across reboots of the system.

Table 4-2 describes the I/O policies that may be set.

Table 4-2DMP I/O policies

Policy	Description
adaptive	This policy attempts to maximize overall I/O throughput from/to the disks by dynamically scheduling I/O on the paths. It is suggested for use where I/O loads can vary over time. For example, I/O from/to a database may exhibit both long transfers (table scans) and short transfers (random look ups). The policy is also useful for a SAN environment where different paths may have different number of hops. No further configuration is possible as this policy is automatically managed by DMP.
	In this example, the adaptive I/O policy is set for the enclosure encl:
	<pre># vxdmpadm setattr enclosure enc1 \ iopolicy=adaptive</pre>
adaptiveminq	Similar to the adaptive policy, except that I/O is scheduled according to the length of the I/O queue on each path. The path with the shortest queue is assigned the highest priority.

Policy	Description
balanced [partitionsize= <i>size</i>]	This policy is designed to optimize the use of caching in disk drives and RAID controllers. The size of the cache typically ranges from 120KB to 500KB or more, depending on the characteristics of the particular hardware. During normal operation, the disks (or LUNs) are logically divided into a number of regions (or partitions), and I/O from/to a given region is sent on only one of the active paths. Should that path fail, the workload is automatically redistributed across the remaining paths.
	You can use the partitionsize attribute to specify the size for the partition. The partition size in blocks is adjustable in powers of 2 from 2 up to 231. A value that is not a power of 2 is silently rounded down to the nearest acceptable value.
	Specifying a partition size of 0 is equivalent to specifying the default partition size.
	The default value for the partition size is 2048 blocks (1024k). Specifying a partition size of 0 is equivalent to the default partition size of 2048 blocks (1024k).
	The default value can be changed by adjusting the value of the dmp_pathswitch_blks_shift tunable parameter.
	See "DMP tunable parameters" on page 191.
	Note: The benefit of this policy is lost if the value is set larger than the cache size.
	For example, the suggested partition size for an Hitachi HDS 9960 A/A array is from 32,768 to 131,072 blocks (16MB to 64MB) for an I/O activity pattern that consists mostly of sequential reads or writes.
	The next example sets the balanced I/O policy with a partition size of 4096 blocks (2MB) on the enclosure enc0:
	<pre># vxdmpadm setattr enclosure enc0 \ iopolicy=balanced partitionsize=4096</pre>
minimumq	This policy sends I/O on paths that have the minimum number of outstanding I/O requests in the queue for a LUN. No further configuration is possible as DMP automatically determines the path with the shortest queue.
	The following example sets the I/O policy to minimumq for a JBOD:
	# vxdmpadm setattr enclosure Disk \
	iopolicy=minimumq
	This is the default I/O policy for all arrays.

 Table 4-2
 DMP I/O policies (continued)

Policy	Description				
priority	This policy is useful when the paths in a SAN have unequal performance, and you want to enforce load balancing manually. You can assign priorities to each path based on your knowledge of the configuration and performance characteristics of the available paths, and of other aspects of your system.				
	See "Setting the attributes of the paths to an enclosure" on page 128.				
	In this example, the I/O policy is set to priority for all SENA arrays:				
	<pre># vxdmpadm setattr arrayname SENA \ iopolicy=priority</pre>				
round-robin	This policy shares I/O equally between the paths in a round-robin sequence. For example, if there are three paths, the first I/O request would use one path, the second would use a different path, the third would be sent down the remaining path, the fourth would go down the first path, and so on. No further configuration is possible as this policy is automatically managed by DMP.				
	The next example sets the I/O policy to round-robin for all Active/Active arrays:				
	<pre># vxdmpadm setattr arraytype A/A \ iopolicy=round-robin</pre>				
singleactive	This policy routes I/O down the single active path. This policy can be configured for A/P arrays with one active path per controller, where the other paths are used in case of failover. If configured for A/A arrays, there is no load balancing across the paths, and the alternate paths are only used to provide high availability (HA). If the current active path fails, I/O is switched to an alternate active path. No further configuration is possible as the single active path is selected by DMP.				
	The following example sets the I/O policy to singleactive for JBOD disks:				
	<pre># vxdmpadm setattr arrayname Disk \ iopolicy=singleactive</pre>				

Table 4-2DMP I/O policies (continued)

Scheduling I/O on the paths of an Asymmetric Active/Active or an ALUA array

You can specify the use_all_paths attribute in conjunction with the adaptive, balanced, minimumq, priority, and round-robin I/O policies to specify whether I/O requests are to be scheduled on the secondary paths in addition to the primary paths of an Asymmetric Active/Active (A/A-A) array or an ALUA array. Depending on the characteristics of the array, the consequent improved load balancing can

increase the total I/O throughput. However, this feature should only be enabled if recommended by the array vendor. It has no effect for array types other than A/A-A or ALUA.

For example, the following command sets the balanced I/O policy with a partition size of 4096 blocks (2MB) on the enclosure enc0, and allows scheduling of I/O requests on the secondary paths:

vxdmpadm setattr enclosure enc0 iopolicy=balanced \ partitionsize=4096 use_all_paths=yes

The default setting for this attribute is use_all_paths=no.

You can display the current setting for <code>use_all_paths</code> for an enclosure, arrayname, or arraytype. To do this, specify the <code>use_all_paths</code> option to the <code>vxdmpadm</code> gettattr command.

```
# vxdmpadm getattr enclosure HDS9500-ALUA0 use_all_paths
```

The use_all_paths attribute only applies to A/A-A arrays and ALUA arrays. For other arrays, the above command displays the message:

Attribute is not applicable for this array.

Example of applying load balancing in a SAN

This example describes how to use Dynamic Multi-Pathing (DMP) to configure load balancing in a SAN environment where there are multiple primary paths to an Active/Passive device through several SAN switches.

As shown in this sample output from the vxdisk list command, the device hdisk18 has eight primary paths:

```
# vxdisk list hdisk18
Device: hdisk18
.
.
.
numpaths: 8
hdisk11 state=enabled type=primary
hdisk12 state=enabled type=primary
hdisk13 state=enabled type=primary
```

```
hdisk14 state=enabled type=primary
hdisk15 state=enabled type=primary
hdisk16 state=enabled type=primary
hdisk17 state=enabled type=primary
hdisk18 state=enabled type=primary
```

In addition, the device is in the enclosure ENCO, belongs to the disk group mydg, and contains a simple concatenated volume myvol1.

The first step is to enable the gathering of DMP statistics:

```
# vxdmpadm iostat start
```

Next, use the dd command to apply an input workload from the volume:

dd if=/dev/vx/rdsk/mydg/myvol1 of=/dev/null &

By running the vxdmpadm iostat command to display the DMP statistics for the device, it can be seen that all I/O is being directed to one path, hdisk18:

vxdmpadm iostat show dmpnodename=hdisk18 interval=5 count=2

```
.
  .

                            0.41
```

The vxdmpadm command is used to display the I/O policy for the enclosure that contains the device:

vxdmpadm getattr enclosure ENC0 iopolicy

This shows that the policy for the enclosure is set to singleactive, which explains why all the I/O is taking place on one path.

To balance the I/O load across the multiple primary paths, the policy is set to round-robin as shown here:

vxdmpadm setattr enclosure ENC0 iopolicy=round-robin # vxdmpadm qetattr enclosure ENC0 iopolicy

The DMP statistics are now reset:

vxdmpadm iostat reset

With the workload still running, the effect of changing the I/O policy to balance the load across the primary paths can now be seen.

vxdmpadm iostat show dmpnodename=hdisk18 interval=5 count=2

•

hdisk18	2042	0	1021	0	0.39	0.00

The enclosure can be returned to the single active I/O policy by entering the following command:

vxdmpadm setattr enclosure ENC0 iopolicy=singleactive

Disabling I/O for paths, controllers, array ports, or DMP nodes

Disabling I/O through a path, HBA controller, array port, or Dynamic Multi-Pathing (DMP) node prevents DMP from issuing I/O requests through the specified path, or the paths that are connected to the specified controller, array port, or DMP node.

If the specified paths have pending I/Os, the vxdmpadm disable command waits until the I/Os are completed before disabling the paths.

DMP does not support the operation to disable I/O for the controllers that use Third-Party Drivers (TPD) for multi-pathing.

To disable I/O for one or more paths, use the following command:

```
# vxdmpadm [-c|-f] disable path=path_name1[,path_name2,path_nameN]
```

To disable I/O for the paths connected to one or more HBA controllers, use the following command:

```
# vxdmpadm [-c|-f] disable ctlr=ctlr name1[,ctlr name2,ctlr nameN]
```

To disable I/O for the paths connected to an array port, use one of the following commands:

```
# vxdmpadm [-c|-f] disable enclosure=enclr_name portid=array_port_ID
# vxdmpadm [-c|-f] disable pwwn=array_port_WWN
```

where the array port is specified either by the enclosure name and the array port ID, or by the array port's worldwide name (WWN) identifier.

The following examples show how to disable I/O on an array port:

```
# vxdmpadm disable enclosure=HDS9500V0 portid=1A
```

```
# vxdmpadm disable pwwn=20:00:00:E0:8B:06:5F:19
```

To disable I/O for a particular path, specify both the controller and the portID, which represent the two ends of the fabric:

```
# vxdmpadm [-c|-f] disable ctlr=ctlr_name enclosure=enclr_name \
portid=array_port_ID
```

To disable I/O for a particular DMP node, specify the DMP node name.

vxdmpadm [-c|-f] disable dmpnodename=dmpnode

You can use the -c option to check if there is only a single active path to the disk.

The last path disable operation fails with **-f** option irrespective whether the device is in use or not.

The disable operation fails if it is issued to a controller that is connected to the root disk through a single path, and there are no root disk mirrors configured on alternate paths. If such mirrors exist, the command succeeds. The disable operation fails if it is issued to a controller that is connected to the swap device through a single path.

Enabling I/O for paths, controllers, array ports, or DMP nodes

Enabling a controller allows a previously disabled path, HBA controller, array port, or Dynamic Multi-Pathing (DMP) node to accept I/O again. This operation succeeds only if the path, controller, array port, or DMP node is accessible to the host, and I/O can be performed on it. When connecting Active/Passive disk arrays, the enable operation results in failback of I/O to the primary path. The enable operation can also be used to allow I/O to the controllers on a system board that was previously detached.

Note: This operation is supported for controllers that are used to access disk arrays on which cluster-shareable disk groups are configured.

DMP does not support the operation to enable I/O for the controllers that use Third-Party Drivers (TPD) for multi-pathing.

To enable I/O for one or more paths, use the following command:

```
# vxdmpadm enable path=path_name1[,path_name2,path_nameN]
```

To enable I/O for the paths connected to one or more HBA controllers, use the following command:

```
# vxdmpadm enable ctlr=ctlr_name1[,ctlr_name2,ctlr_nameN]
```

To enable I/O for the paths connected to an array port, use one of the following commands:

```
# vxdmpadm enable enclosure=enclr_name portid=array_port_ID
# vxdmpadm enable pwwn=array_port_WWN
```

where the array port is specified either by the enclosure name and the array port ID, or by the array port's worldwide name (WWN) identifier.

The following are examples of using the command to enable I/O on an array port:

```
# vxdmpadm enable enclosure=HDS9500V0 portid=1A
# vxdmpadm enable pwwn=20:00:00:E0:8B:06:5F:19
```

To enable I/O for a particular path, specify both the controller and the portID, which represent the two ends of the fabric:

```
# vxdmpadm enable ctlr=ctlr_name enclosure=enclr_name \
portid=array_port_ID
```

To enable I/O for a particular DMP node, specify the DMP node name.

vxdmpadm enable dmpnodename=dmpnode

Renaming an enclosure

The vxdmpadm setattr command can be used to assign a meaningful name to an existing enclosure, for example:

vxdmpadm setattr enclosure emc0 name=GRP1

This example changes the name of an enclosure from emc0 to GRP1.

Note: The maximum length of the enclosure name prefix is 23 characters.

The following command shows the changed name:

```
# vxdmpadm listenclosure all
```

ENCLR_NAME	ENCLR_TYPE	ENCLR_SNO	STATUS	ARRAY_TYPE	LUN_COUNT	F
						==
Disk	Disk	DISKS	CONNECTED	Disk	6	-
GRP1	EMC	000292601383	CONNECTED	A/A	1	5
hitachi_usp-vm0	Hitachi_USP-VM	25847	CONNECTED	A/A	1	6
emc_clariion0	EMC_CLARiiON	CK20007040035	CONNECTED	CLR-A/PF	2	0

Configuring the response to I/O failures

You can configure how Dynamic Multi-Pathing (DMP) responds to failed I/O requests on the paths to a specified enclosure, disk array name, or type of array. By default, DMP is configured to retry a failed I/O request up to five minutes on various active paths.

To display the current settings for handling I/O request failures that are applied to the paths to an enclosure, array name, or array type, use the vxdmpadm getattr command.

See "Displaying recovery option values" on page 144.

To set a limit for the number of times that DMP attempts to retry sending an I/O request on a path, use the following command:

```
# vxdmpadm setattr \
  {enclosure enc-name|arrayname name|arraytype type} \
  recoveryoption=fixedretry retrycount=n
```

The value of the argument to retrycount specifies the number of retries to be attempted before DMP reschedules the I/O request on another available path, or fails the request altogether.

As an alternative to specifying a fixed number of retries, you can specify the amount of time DMP allows for handling an I/O request. If the I/O request does not succeed within that time, DMP fails the I/O request. To specify an *iotimeout* value, use the following command:

```
# vxdmpadm setattr \
{enclosure enc-name|arrayname name|arraytype type} \
recoveryoption=timebound iotimeout=seconds
```

The default value of iotimeout is 300 seconds. For some applications such as Oracle, it may be desirable to set iotimeout to a larger value. The iotimeout value for DMP should be greater than the I/O service time of the underlying operating system layers.

Note: The fixedretry and timebound settings are mutually exclusive.

The following example configures time-bound recovery for the enclosure enc0, and sets the value of iotimeout to 360 seconds:

vxdmpadm setattr enclosure enc0 recoveryoption=timebound \
iotimeout=360

The next example sets a fixed-retry limit of 10 for the paths to all Active/Active arrays:

vxdmpadm setattr arraytype A/A recoveryoption=fixedretry \
retrycount=10

Specifying recoveryoption=default resets DMP to the default settings for recovery.

For example, the following command sets the default settings:

```
# vxdmpadm setattr arraytype A/A recoveryoption=default
```

For PCI devices, the default settings are recoveryoption=fixedretry retrycount=5.

For all other devices, the default settings are recoveryoption=timebound iotimeout=300

Specifying recovery option=defaultalso has the effect of configuring I/O throttling with the default settings.

See "Configuring the I/O throttling mechanism" on page 142.

Note: The response to I/O failure settings is persistent across reboots of the system.

Configuring the I/O throttling mechanism

By default, Dynamic Multi-Pathing (DMP) is configured with I/O throttling turned off for all paths. To display the current settings for I/O throttling that are applied to the paths to an enclosure, array name, or array type, use the vxdmpadm getattr command.

See "Displaying recovery option values" on page 144.

If enabled, I/O throttling imposes a small overhead on CPU and memory usage because of the activity of the statistics-gathering daemon. If I/O throttling is disabled, the daemon no longer collects statistics, and remains inactive until I/O throttling is re-enabled.

To turn off I/O throttling, use the following form of the vxdmpadm setattr command:

```
# vxdmpadm setattr \
{enclosure enc-name|arrayname name|arraytype type} \
recoveryoption=nothrottle
```

The following example shows how to disable I/O throttling for the paths to the enclosure enc0:

vxdmpadm setattr enclosure enc0 recoveryoption=nothrottle

The vxdmpadm setattr command can be used to enable I/O throttling on the paths to a specified enclosure, disk array name, or type of array:

```
# vxdmpadm setattr \
```

```
{enclosure enc-name|arrayname name|arraytype type}\
recoveryoption=throttle [iotimeout=seconds]
```

If the iotimeout attribute is specified, its argument specifies the time in seconds that DMP waits for an outstanding I/O request to succeed before invoking I/O throttling on the path. The default value of iotimeout is 10 seconds. Setting iotimeout to a larger value potentially causes more I/O requests to become queued up in the SCSI driver before I/O throttling is invoked.

The following example sets the value of intimeout to 60 seconds for the enclosure enco:

vxdmpadm setattr enclosure enc0 recoveryoption=throttle \
iotimeout=60

Specify recoveryoption=default to reset I/O throttling to the default settings, as follows:

vxdmpadm setattr arraytype A/A recoveryoption=default

The above command configures the default behavior, corresponding to recoveryoption=nothrottle. The above command also configures the default behavior for the response to I/O failures.

See "Configuring the response to I/O failures" on page 140.

Note: The I/O throttling settings are persistent across reboots of the system.

Configuring Subpaths Failover Groups (SFG)

The Subpaths Failover Groups (SFG) feature can be turned on or off using the tunable dmp_sfg_threshold. The default value of the tunable is 1, which represents that the feature is on.

To turn off the feature, set the tunable dmp sfg threshold value to 0:

```
# vxdmpadm settune dmp_sfg_threshold=0
```

To turn on the feature, set the dmp_sfg_threshold value to the required number of path failures that triggers SFG.

vxdmpadm settune dmp_sfg_threshold=N

To see the Subpaths Failover Groups ID, use the following command:

Configuring Low Impact Path Probing (LIPP)

The Low Impact Path Probing (LIPP) feature can be turned on or off using the vxdmpadm settune command:

```
# vxdmpadm settune dmp_low_impact_probe=[on|off]
```

Path probing will be optimized by probing a subset of paths connected to the same HBA and array port. The size of the subset of paths can be controlled by the dmp probe threshold tunable. The default value is set to 5.

```
# vxdmpadm settune dmp_probe_threshold=N
```

Displaying recovery option values

To display the current settings for handling I/O request failures that are applied to the paths to an enclosure, array name, or array type, use the following Dynamic Multi-Pathing (DMP) command:

```
# vxdmpadm getattr \
{enclosure enc-name|arrayname name|arraytype type} \
recoveryoption
```

The following example shows the vxdmpadm getattr command being used to display the recoveryoption option values that are set on an enclosure.

The command output shows the default and current policy options and their values.

Table 4-3 summarizes the possible recovery option settings for retrying I/O after an error.

Table 4-3	Recovery	options f	or retrying	I/O	after an error
-----------	----------	-----------	-------------	-----	----------------

Recovery option	Possible settings	Description
recoveryoption=fixedretry	Fixed-Retry (retrycount)	DMP retries a failed I/O request for the specified number of times if I/O fails.
recoveryoption=timebound	Timebound (iotimeout)	DMP retries a failed I/O request for the specified time in seconds if I/O fails.

Table 4-4 summarizes the possible recovery option settings for throttling I/O.

 Table 4-4
 Recovery options for I/O throttling

Recovery option	Possible settings	Description
recoveryoption=nothrottle	None	I/O throttling is not used.

Recovery option	Possible settings	Description
recoveryoption=throttle	Timebound (iotimeout)	DMP throttles the path if an I/O request does not return within the specified time in seconds.

Table 4-4Recovery options for I/O throttling (continued)

Configuring DMP path restoration policies

Dynamic Multi-Pathing (DMP) maintains a kernel task that re-examines the condition of paths at a specified interval. The type of analysis that is performed on the paths depends on the checking policy that is configured.

Note: The DMP path restoration task does not change the disabled state of the path through a controller that you have disabled using vxdmpadm disable.

When configuring DMP path restoration policies, you must stop the path restoration thread, and then restart it with new attributes.

See "Stopping the DMP path restoration thread" on page 146.

Use the vxdmpadm settune dmp_restore_policy command to configure one of the following restore policies. The policy remains in effect until the restore thread is stopped or the values are changed using the vxdmpadm settune command.

check_all

The path restoration thread analyzes all paths in the system and revives the paths that are back online, as well as disabling the paths that are inaccessible. The command to configure this policy is:

vxdmpadm settune dmp_restore_policy=check_all

check_alternate

The path restoration thread checks that at least one alternate path is healthy. It generates a notification if this condition is not met. This policy avoids inquiry commands on all healthy paths, and is less costly than check_all in cases where a large number of paths are available. This policy is the same as check_all if there are only two paths per DMP node. The command to configure this policy is:

vxdmpadm settune dmp_restore_policy=check_alternate

check_disabled

This is the default path restoration policy. The path restoration thread checks the condition of paths that were previously disabled due to hardware failures, and revives them if they are back online. The command to configure this policy is:

vxdmpadm settune dmp_restore_policy=check_disabled

check_periodic

The path restoration thread performs check_all once in a given number of cycles, and check_disabled in the remainder of the cycles. This policy may lead to periodic slowing down (due to check_all) if a large number of paths are available. The command to configure this policy is:

vxdmpadm settune dmp_restore_policy=check_periodic

The default number of cycles between running the check all policy is 10.

The dmp_restore_interval tunable parameter specifies how often the path restoration thread examines the paths. For example, the following command sets the polling interval to 400 seconds:

vxdmpadm settune dmp_restore_interval=400

The settings are immediately applied and are persistent across reboots. Use the vxdmpadm gettune command to view the current settings.

See "DMP tunable parameters" on page 191.

If the vxdmpadm start restore command is given without specifying a policy or interval, the path restoration thread is started with the persistent policy and interval settings previously set by the administrator with the vxdmpadm settune command. If the administrator has not set a policy or interval, the system defaults are used. The system default restore policy is check_disabled. The system default interval is 300 seconds.

Warning: Decreasing the interval below the system default can adversely affect system performance.

Stopping the DMP path restoration thread

Use the following command to stop the Dynamic Multi-Pathing (DMP) path restoration thread:

```
# vxdmpadm stop restore
```

Warning: Automatic path failback stops if the path restoration thread is stopped.

Displaying the status of the DMP path restoration thread

Use the vxdmpadm gettune command to display the tunable parameter values that show the status of the Dynamic Multi-Pathing (DMP) path restoration thread. These tunables include:

dmp_restore_state the status of the automatic path restoration kernel thread.

dmp_restore_interval the polling interval for the DMP path restoration thread.

dmp_restore_policy the policy that DMP uses to check the condition of paths.

To display the status of the DMP path restoration thread

- Use the following commands:
 - # vxdmpadm gettune dmp_restore_state
 - # vxdmpadm gettune dmp_restore_interval
 - # vxdmpadm gettune dmp_restore_policy

Configuring Array Policy Modules

Dynamic Multi-Pathing (DMP) provides Array Policy Modules (APMs) for use with an array. An APM is a dynamically loadable kernel module (or plug-in) that defines array-specific procedures and commands to:

- Select an I/O path when multiple paths to a disk within the array are available.
- Select the path failover mechanism.
- Select the alternate path in the case of a path failure.
- Put a path change into effect.
- Respond to SCSI reservation or release requests.

DMP supplies default procedures for these functions when an array is registered. An APM may modify some or all of the existing procedures that DMP provides, or that another version of the APM provides.

You can use the following command to display all the APMs that are configured for a system:

vxdmpadm listapm all

The output from this command includes the file name of each module, the supported array type, the APM name, the APM version, and whether the module is currently loaded and in use.

To see detailed information for an individual module, specify the module name as the argument to the command:

```
# vxdmpadm listapm module_name
```

To add and configure an APM, use the following command:

```
# vxdmpadm -a cfgapm module_name [attr1=value1 \
      [attr2=value2 ...]]
```

The optional configuration attributes and their values are specific to the APM for an array. Consult the documentation from the array vendor for details.

Note: By default, DMP uses the most recent APM that is available. Specify the -u option instead of the -a option if you want to force DMP to use an earlier version of the APM. The current version of an APM is replaced only if it is not in use.

Specify the -r option to remove an APM that is not currently loaded:

```
# vxdmpadm -r cfgapm module_name
```

See the vxdmpadm(1M) manual page.

Chapter

Administering disks

This chapter includes the following topics:

- About disk management
- Discovering and configuring newly added disk devices
- Changing the disk device naming scheme
- Discovering the association between enclosure-based disk names and OS-based disk names

About disk management

Dynamic Multi-Pathing (DMP) is used to administer multiported disk arrays.

See "How DMP works" on page 13.

DMP uses the Device Discovery Layer (DDL) to handle device discovery and configuration of disk arrays. DDL discovers disks and their attributes that are required for DMP operations. Use the vxddladm utility to administer the DDL.

See "How to administer the Device Discovery Layer" on page 155.

Discovering and configuring newly added disk devices

When you physically connect new disks to a host or when you zone new Fibre Channel devices to a host, you can use the vxdctl enable command to rebuild the volume device node directories and to update the Dynamic Multi-Pathing (DMP) internal database to reflect the new state of the system.

To reconfigure the DMP database, first run cfgmgr to make the operating system recognize the new disks, and then invoke the vxdctl enable command.

You can also use the vxdisk scandisks command to scan devices in the operating system device tree, and to initiate dynamic reconfiguration of multipathed disks.

If you want DMP to scan only for new devices that have been added to the system, and not for devices that have been enabled or disabled, specify the -f option to either of the commands, as shown here:

- # vxdctl -f enable
- # vxdisk -f scandisks

However, a complete scan is initiated if the system configuration has been modified by changes to:

- Installed array support libraries.
- The list of devices that are excluded from use by VxVM.
- DISKS (JBOD), SCSI3, or foreign device definitions.

See the vxdct1(1M) manual page.

See the vxdisk(1M) manual page.

Partial device discovery

Dynamic Multi-Pathing (DMP) supports partial device discovery where you can include or exclude paths to a physical disk from the discovery process.

The vxdisk scandisks command rescans the devices in the OS device tree and triggers a DMP reconfiguration. You can specify parameters to vxdisk scandisks to implement partial device discovery. For example, this command makes DMP discover newly added devices that were unknown to it earlier:

```
# vxdisk scandisks new
```

The next example discovers fabric devices:

```
# vxdisk scandisks fabric
```

The following command scans for the devices hdisk10 and hdisk11:

```
# vxdisk scandisks device=hdisk10,hdisk11
```

Alternatively, you can specify a ! prefix character to indicate that you want to scan for all devices except those that are listed.

Note: The ! character is a special character in some shells. The following examples show how to escape it in a bash shell.

vxdisk scandisks \!device=hdisk10,hdisk11

You can also scan for devices that are connected (or not connected) to a list of logical or physical controllers. For example, this command discovers and configures all devices except those that are connected to the specified logical controllers:

vxdisk scandisks \!ctlr=scsi1,scsi2

The next command discovers devices that are connected to the specified physical controller:

vxdisk scandisks pctlr=10-60

The items in a list of physical controllers are separated by + characters.

You can use the command vxdmpadm getctlr all to obtain a list of physical controllers.

You should specify only one selection argument to the vxdisk scandisks command. Specifying multiple options results in an error.

See the vxdisk(1M) manual page.

About discovering disks and dynamically adding disk arrays

Dynamic Multi-Pathing (DMP) uses array support libraries (ASLs) to provide array-specific support for multi-pathing. An array support library (ASL) is a dynamically loadable shared library (plug-in for DDL). The ASL implements hardware-specific logic to discover device attributes during device discovery. DMP provides the device discovery layer (DDL) to determine which ASLs should be associated to each disk array.

In some cases, DMP can also provide basic multi-pathing and failover functionality by treating LUNs as disks (JBODs).

How DMP claims devices

For fully optimized support of any array and for support of more complicated array types, Dynamic Multi-Pathing (DMP) requires the use of array-specific array support libraries (ASLs), possibly coupled with array policy modules (APMs). ASLs and APMs effectively are array-specific plug-ins that allow close tie-in of DMP with any specific array model.

See the Hardware Compatibility List for the complete list of supported arrays.

http://www.symantec.com/docs/TECH211575

During device discovery, the DDL checks the installed ASL for each device to find which ASL claims the device.

If no ASL is found to claim the device, the DDL checks for a corresponding JBOD definition. You can add JBOD definitions for unsupported arrays to enable DMP to provide multi-pathing for the array. If a JBOD definition is found, the DDL claims the devices in the DISKS category, which adds the LUNs to the list of JBOD (physical disk) devices used by DMP. If the JBOD definition includes a cabinet number, DDL uses the cabinet number to group the LUNs into enclosures.

See "Adding unsupported disk arrays to the DISKS category" on page 163.

DMP can provide basic multi-pathing to arrays that comply with the Asymmetric Logical Unit Access (ALUA) standard, even if there is no ASL or JBOD definition. DDL claims the LUNs as part of the aluadisk enclosure. The array type is shown as ALUA. Adding a JBOD definition also enables you to group the LUNs into enclosures.

Disk categories

Disk arrays that have been certified for use with Dynamic Multi-Pathing (DMP) are supported by an array support library (ASL), and are categorized by the vendor ID string that is returned by the disks (for example, "HITACHI").

Disks in JBODs that are capable of being multi-pathed by DMP, are placed in the DISKS category. Disks in unsupported arrays can also be placed in the DISKS category.

See "Adding unsupported disk arrays to the DISKS category" on page 163.

Disks in JBODs that do not fall into any supported category, and which are not capable of being multi-pathed by DMP are placed in the <code>OTHER_DISKS</code> category.

Adding DMP support for a new disk array

You can dynamically add support for a new type of disk array. The support comes in the form of Array Support Libraries (ASLs) that are developed by Symantec. Symantec provides support for new disk arrays through updates to the VRTSaslapm fileset. To determine if an updated VRTSaslapm fileset is available for download, refer to the hardware compatibility list tech note. The hardware compatibility list provides a link to the latest fileset for download and instructions for installing the VRTSaslapm fileset. You can upgrade the VRTSaslapm fileset while the system is online; you do not need to stop the applications.

To access the hardware compatibility list, go to the following URL:

http://www.symantec.com/docs/TECH211575

Each VRTSaslapm fileset is specific for the Dynamic Multi-Pathing version. Be sure to install the VRTSaslapm fileset that supports the installed version of Dynamic Multi-Pathing.

The new disk array does not need to be already connected to the system when the VRTSaslapm fileset is installed. If any of the disks in the new disk array are subsequently connected, you need to trigger OS device discovery using the cfgmgr command and then trigger DDL device discovery using the vxdctl enable command.

See "Adding new LUNs dynamically to a target ID" on page 174.

If you need to remove the latest VRTSaslapm fileset, you can revert to the previously installed version. For the detailed procedure, refer to the *Veritas InfoScale Troubleshooting Guide*.

Enabling discovery of new disk arrays

The vxdctl enable command scans all of the disk devices and their attributes, updates the DMP device list, and reconfigures DMP with the new device database. There is no need to reboot the host.

Warning: This command ensures that Dynamic Multi-Pathing is set up correctly for the array. Otherwise, VxVM treats the independent paths to the disks as separate devices, which can result in data corruption.

To enable discovery of a new disk array

- Type the following command:
 - # vxdctl enable

Discovering renamed devices on AIX

Starting with AIX 6.1TL6, AIX provides a feature to rename a device using the rendev command. You can now specify user-defined names instead of the traditional hdisk name.

Dynamic Multi-Pathing (DMP) now can discover the renamed devices. DMP supports device renaming for both enclosure-based naming (EBN) and operating system naming (OSN). Before renaming a device, remove the DMP node from VxVM/DMP control.

You can use the vxdmpadm command to enable and disable the renamed path.

The following features are not supported with renamed devices:

- Enabling rootability
- Migrating LVM to VxVM using the vxconvert command

Hot relocation

To rename a device and bring it back to VxVM/DMP control

 Remove the DMP node from VxVM/DMP control. For example, the following output shows that the DMP node name ds4100-0 9 refers to the device hdisk1.

Remove hdisk1 from VxVM/DMP control:

```
# vxdisk rm ds4100-0_9
```

2 Rename the device.

```
# rendev -1 hdisk1 -n myhdisk1
```

- 3 Scan the devices.
 - # vxdisk scandisks
- **4** Verify that the DMP node now refers to the new device name.

About third-party driver coexistence

The third-party driver (TPD) coexistence feature of Dynamic Multi-Pathing (DMP) allows I/O that is controlled by some third-party multi-pathing drivers to bypass Dynamic Multi-Pathing (DMP) while retaining the monitoring capabilities of DMP. If a suitable Array Support Library (ASL) is available and installed, devices that use TPDs can be discovered without requiring you to set up a specification file, or to run a special command. The TPD coexistence feature of DMP permits coexistence without requiring any change in a third-party multi-pathing driver.

See "Displaying information about devices controlled by third-party drivers" on page 117.

How to administer the Device Discovery Layer

The Device Discovery Layer (DDL) allows dynamic addition of disk arrays. DDL discovers disks and their attributes that are required for Dynamic Multi-Pathing (DMP) operations.

The DDL is administered using the vxddladm utility to perform the following tasks:

- List the hierarchy of all the devices discovered by DDL including iSCSI devices.
- List all the Host Bus Adapters including iSCSI.
- List the ports configured on a Host Bus Adapter.
- List the targets configured from a Host Bus Adapter.
- List the devices configured from a Host Bus Adapter.
- Get or set the iSCSI operational parameters.
- List the types of arrays that are supported.
- Add support for an array to DDL.
- Remove support for an array from DDL.
- List information about excluded disk arrays.
- List disks that are claimed in the DISKS (JBOD) category.
- Add disks from different vendors to the DISKS category.
- Remove disks from the DISKS category.
- Add disks as foreign devices.

The following sections explain these tasks in more detail.

See the vxddladm(1M) manual page.

Listing all the devices including iSCSI

You can display the hierarchy of all the devices discovered by DDL, including iSCSI devices.

To list all the devices including iSCSI

• Type the following command:

```
# vxddladm list
```

The following is a sample output:

```
HBA fscsi0 (20:00:00:E0:8B:19:77:BE)
Port fscsi0_p0 (50:0A:09:80:85:84:9D:84)
Target fscsi0_p0_t0 (50:0A:09:81:85:84:9D:84)
LUN hdisk1
...
HBA iscsi0 (iqn.1986-03.com.sun:01:0003ba8ed1b5.45220f80)
Port iscsi0_p0 (10.216.130.10:3260)
Target iscsi0_p0_t0 (iqn.1992-08.com.netapp:sn.84188548)
LUN hdisk2
LUN hdisk3
Target iscsi0_p0_t1 (iqn.1992-08.com.netapp:sn.84190939)
...
```

Listing all the Host Bus Adapters including iSCSI

You can obtain information about all the Host Bus Adapters (HBAs) configured on the system, including iSCSI adapters.

Table 5-1 shows the HBA information.

Field	Description
Driver	Driver controlling the HBA.
Firmware	Firmware version.
Discovery	The discovery method employed for the targets.
State	Whether the device is Online or Offline.
Address	The hardware address.

Table 5-1HBA information

To list all the Host Bus Adapters including iSCSI

 Use the following command to list all of the HBAs, including iSCSI devices, configured on the system:

```
# vxddladm list hbas
```

Listing the ports configured on a Host Bus Adapter

You can obtain information about all the ports configured on an HBA. The display includes the following information:

HBA-ID	The parent HBA.
State	Whether the device is Online or Offline.
Address	The hardware address.

To list the ports configured on a Host Bus Adapter

• Use the following command to obtain the ports configured on an HBA:

Listing the targets configured from a Host Bus Adapter or a port

You can obtain information about all the targets configured from a Host Bus Adapter or a port.

Table 5-2 shows the target information.

Table 5-2Target information

Field	Description
Alias	The alias name, if available.
HBA-ID	Parent HBA or port.
State	Whether the device is Online or Offline.
Address	The hardware address.

To list the targets

To list all of the targets, use the following command:

vxddladm list targets

The following is a sample output:

To list the targets configured from a Host Bus Adapter or port

You can filter based on a HBA or port, using the following command:

vxddladm list targets [hba=hba_name|port=port_name]

For example, to obtain the targets configured from the specified HBA:

vxddladm list targets hba=fscsi0

Listing the devices configured from a Host Bus Adapter and target

You can obtain information about all the devices configured from a Host Bus Adapter.

Table 5-3 shows the device information.

Field	Description
Device	The device name.
Target-ID	The parent target.
State	Whether the device is Online or Offline.
DDL status	Whether the device is claimed by DDL. If claimed, the output also displays the ASL name.

Table 5-3Device information

To list the devices configured from a Host Bus Adapter

• To obtain the devices configured, use the following command:

```
# vxddladm list devices
```

To list the devices configured from a Host Bus Adapter and target

 To obtain the devices configured from a particular HBA and target, use the following command:

```
# vxddladm list devices target=target_name
```

Getting or setting the iSCSI operational parameters

DDL provides an interface to set and display certain parameters that affect the performance of the iSCSI device path. However, the underlying OS framework must support the ability to set these values. The vxddladm set command returns an error if the OS support is not available.

Parameter	Default value	Minimum value	Maximum value
DataPDUInOrder	yes	no	yes
DataSequenceInOrder	yes	no	yes
DefaultTime2Retain	20	0	3600
DefaultTime2Wait	2	0	3600
ErrorRecoveryLevel	0	0	2
FirstBurstLength	65535	512	16777215
InitialR2T	yes	no	yes
ImmediateData	yes	no	yes

 Table 5-4
 Parameters for iSCSI devices

Parameter	Default value	Minimum value	Maximum value
MaxBurstLength	262144	512	16777215
MaxConnections	1	1	65535
MaxOutStandingR2T	1	1	65535
MaxRecvDataSegmentLength	8182	512	16777215

 Table 5-4
 Parameters for iSCSI devices (continued)

To get the iSCSI operational parameters on the initiator for a specific iSCSI target

• Type the following commands:

vxddladm getiscsi target=tgt-id {all | parameter}

You can use this command to obtain all the iSCSI operational parameters.

vxddladm getiscsi target=iscsi0_p2_t0

The following is a sample output:

PARAMETER	CURRENT	DEFAULT	MIN	MAX
DataPDUInOrder	yes	yes	no	yes
DataSequenceInOrder	yes	yes	no	yes
DefaultTime2Retain	20	20	0	3600
DefaultTime2Wait	2	2	0	3600
ErrorRecoveryLevel	0	0	0	2
FirstBurstLength	65535	65535	512	16777215
InitialR2T	yes	yes	no	yes
ImmediateData	yes	yes	no	yes
MaxBurstLength	262144	262144	512	16777215
MaxConnections	1	1	1	65535
MaxOutStandingR2T	1	1	1	65535
MaxRecvDataSegmentLengt	ch 8192	8182	512	16777215

To set the iSCSI operational parameters on the initiator for a specific iSCSI target

• Type the following command:

vxddladm setiscsi target=tgt-id parameter=value

Listing all supported disk arrays

Use this procedure to obtain values for the $\tt vid$ and $\tt pid$ attributes that are used with other forms of the <code>vxddladm</code> command.

To list all supported disk arrays

- Use the following command:
 - # vxddladm listsupport all

Excluding support for a disk array library

You can exclude support for disk arrays that depends on a particular disk array library. You can also exclude support for disk arrays from a particular vendor.

To exclude support for a disk array library

 To exclude support for a disk array library, specify the array library to the following command.

```
# vxddladm excludearray libname=libname
```

You can also exclude support for disk arrays from a particular vendor, as shown in this example:

```
# vxddladm excludearray vid=ACME pid=X1
```

Re-including support for an excluded disk array library

If you previously excluded support for all arrays that depend on a particular disk array library, use this procedure to include the support for those arrays. This procedure removes the library from the exclude list.

To re-include support for an excluded disk array library

- If you have excluded support for all arrays that depend on a particular disk array library, you can use the includearray keyword to remove the entry from the exclude list.
 - # vxddladm includearray libname=libname

This command adds the array library to the database so that the library can once again be used in device discovery. If vxconfigd is running, you can use the vxdisk scandisks command to discover the arrays and add their details to the database.

Listing excluded disk arrays

To list all disk arrays that are currently excluded from use by Veritas Volume Manager (VxVM)

- Type the following command:
 - # vxddladm listexclude

Listing disks claimed in the DISKS category

To list disks that are claimed in the DISKS (JBOD) category

• Type the following command:

```
# vxddladm listjbod
```

Displaying details about an Array Support Library

Dynamic Multi-Pathing (DMP) enables you to display details about the Array Support Libraries (ASL).

To display details about an Array Support Library

• Type the following command:

```
# vxddladm listsupport libname=library_name.so
```

This command displays the vendor IDs (VIDs), product IDs (PIDs) for the arrays, array types (for example, A/A or A/P), and array names. The following is sample output.

<pre># vxddladm listsupport libname=libvxfujitsu.so</pre>				
ATTR_NAME	ATTR_VALUE			
LIBNAME	libvxfujitsu.so			
VID	vendor			
PID	GR710, GR720, GR730			
	GR740, GR820, GR840			
ARRAY_TYPE	A/A, A/P			
ARRAY_NAME	FJ_GR710, FJ_GR720, FJ_GR730			
	FJ_GR740, FJ_GR820, FJ_GR840			

Adding unsupported disk arrays to the DISKS category

Disk arrays should be added as JBOD devices if no Array Support Library (ASL) is available for the array.

JBODs are assumed to be Active/Active (A/A) unless otherwise specified. If a suitable ASL is not available, an A/A-A, A/P, or A/PF array must be claimed as an Active/Passive (A/P) JBOD to prevent path delays and I/O failures. If a JBOD is ALUA-compliant, it is added as an ALUA array.

See "How DMP works" on page 13.

Warning: This procedure ensures that Dynamic Multi-Pathing (DMP) is set up correctly on an array that is not supported by Veritas Volume Manager (VxVM). Otherwise, VxVM treats the independent paths to the disks as separate devices, which can result in data corruption.

To add an unsupported disk array to the DISKS category

1 Use the following command to identify the vendor ID and product ID of the disks in the array:

```
# /etc/vx/diag.d/vxscsiinq device_name
```

where *device_name* is the device name of one of the disks in the array. Note the values of the vendor ID (VID) and product ID (PID) in the output from this command. For Fujitsu disks, also note the number of characters in the serial number that is displayed.

The following example output shows that the vendor ID is **SEAGATE** and the product ID is **ST318404LSUN18G**.

Vendor id (VID)	: SEAGATE
Product id (PID)	: ST318404LSUN18G
Revision	: 8507
Serial Number	: 0025T0LA3H

- 2 Stop all applications, such as databases, from accessing VxVM volumes that are configured on the array, and unmount all file systems and Storage Checkpoints that are configured on the array.
- **3** If the array is of type A/A-A, A/P, or A/PF, configure it in autotrespass mode.

4 Enter the following command to add a new JBOD category:

```
# vxddladm addjbod vid=vendorid [pid=productid] \
[serialnum=opcode/pagecode/offset/length] \
[cabinetnum=opcode/pagecode/offset/length] policy={aa|ap}]
```

where *vendorid* and *productid* are the VID and PID values that you found from the previous step. For example, *vendorid* might be FUJITSU, IBM, or SEAGATE. For Fujitsu devices, you must also specify the number of characters in the serial number as the length argument (for example, 10). If the array is of type A/A-A, A/P, or A/PF, you must also specify the policy=ap attribute.

Continuing the previous example, the command to define an array of disks of this type as a JBOD would be:

vxddladm addjbod vid=SEAGATE pid=ST318404LSUN18G

5 Use the vxdctl enable command to bring the array under VxVM control.

```
# vxdctl enable
```

See "Enabling discovery of new disk arrays" on page 153.

6 To verify that the array is now supported, enter the following command:

vxddladm listjbod

The following is sample output from this command for the example array:

VID	D PID SerialNum		CabinetNum	Policy
		(Cmd/PageCode/off/len)	(Cmd/PageCode/	off/len)
SEAGATE	ALL PIDs	18/-1/36/12	18/-1/10/11	Disk
SUN	SESS01	18/-1/36/12	18/-1/12/11	Disk

7 To verify that the array is recognized, use the vxdmpadm listenclosure command as shown in the following sample output for the example array:

vxdmpadm listenclosure

ENCLR_NAME ENCLR_TYPE ENCLR_SNO STATUS ARRAY_TYPE LUN_COUNT FIRMWARE

Disk Disk DISKS CONNECTED Disk 2 -

The enclosure name and type for the array are both shown as being set to Disk. You can use the vxdisk list command to display the disks in the array:

vxdisk list

DEVICE	TYPE	DISK	GROUP	STATUS
Disk_0	auto:none	-	-	online invalid
Disk_1	auto:none	-	-	online invalid

8 To verify that the DMP paths are recognized, use the vxdmpadm getdmpnode command as shown in the following sample output for the example array:

vxdmpadm getdmpnode enclosure=Disk

NAME	STATE	ENCLR-TYPE	PATHS	ENBL	DSBL	ENCLR-NAME
Disk_0	ENABLED	Disk	2	2	0	Disk
Disk_1	ENABLED	Disk	2	2	0	Disk

The output in this example shows that there are two paths to the disks in the array.

For more information, enter the command vxddladm help addjbod.

See the vxddladm(1M) manual page.

See the vxdmpadm(1M) manual page.

Removing disks from the DISKS category

Use the procedure in this section to remove disks from the DISKS category.

To remove disks from the DISKS category

 Use the vxddladm command with the rmjbod keyword. The following example illustrates the command for removing disks that have the vendor id of SEAGATE:

vxddladm rmjbod vid=SEAGATE

Foreign devices

The Device Discovery Layer (DDL) may not be able to discover some devices that are controlled by third-party drivers, such as those that provide multi-pathing or RAM disk capabilities. Such foreign devices can be made available as simple disks to Veritas Volume Manager (VxVM) by using the vxddladm addforeign command. This also has the effect of bypassing DMP for handling I/O. The following example shows how to add entries for block and character devices in the specified directories:

```
# vxddladm addforeign blockdir=/dev/foo/dsk chardir=/dev/foo/rdsk
```

By default, this command suppresses any entries for matching devices in the OS-maintained device tree that are found by the autodiscovery mechanism. You can override this behavior by using the -f and -n options as described on the vxddladm(1M) manual page.

After adding entries for the foreign devices, use either the vxdisk scandisks or the vxdctl enable command to discover the devices as simple disks. These disks then behave in the same way as autoconfigured disks.

Foreign device support has the following limitations:

- A foreign device is always considered as a disk with a single path. Unlike an autodiscovered disk, it does not have a DMP node.
- It is not supported for shared disk groups in a clustered environment. Only standalone host systems are supported.
- It is not supported for Persistent Group Reservation (PGR) operations.
- It is not under the control of DMP, so enabling of a failed disk cannot be automatic, and DMP administrative commands are not applicable.
- Enclosure information is not available to VxVM. This can reduce the availability
 of any disk groups that are created using such devices.
- The I/O fencing and Cluster File System features are not supported for foreign devices.

If a suitable ASL is available and installed for an array, these limitations are removed.

See "About third-party driver coexistence" on page 154.

Changing the disk device naming scheme

You can either use enclosure-based naming for disks or the operating system's naming scheme. DMP commands display device names according to the current naming scheme.

The default naming scheme is enclosure-based naming (EBN).

When you use Dynamic Multi-Pathing (DMP) with native volumes, the disk naming scheme must be EBN, the use_avid attribute must be on, and the persistence attribute must be set to yes.

To change the disk-naming scheme

 Select Change the disk naming scheme from the vxdiskadm main menu to change the disk-naming scheme that you want DMP to use. When prompted, enter v to change the naming scheme.

OR

Change the naming scheme from the command line. Use the following command to select enclosure-based naming:

```
# vxddladm set namingscheme=ebn [persistence={yes|no}] \
[use_avid={yes|no}] [lowercase={yes|no}]
```

Use the following command to select operating system-based naming:

```
# vxddladm set namingscheme=osn [persistence={yes|no}] \
[lowercase=yes|no]
```

The optional persistence argument allows you to select whether the names of disk devices that are displayed by DMP remain unchanged after disk hardware has been reconfigured and the system rebooted. By default, enclosure-based naming is persistent. Operating system-based naming is not persistent by default.

To change only the naming persistence without changing the naming scheme, run the vxddladm set namingscheme command for the current naming scheme, and specify the persistence attribute.

By default, the names of the enclosure are converted to lowercase, regardless of the case of the name specified by the ASL. The enclosure-based device names are therefore in lowercase. Set the <code>lowercase=no</code> option to suppress the conversion to lowercase.

For enclosure-based naming, the use_avid option specifies whether the Array Volume ID is used for the index number in the device name. By default, use_avid=yes, indicating the devices are named as *enclosure_avid*. If use_avid is set to no, DMP devices are named as *enclosure_index*. The index number is assigned after the devices are sorted by LUN serial number.

The change is immediate whichever method you use.

See "Regenerating persistent device names" on page 168.

Displaying the disk-naming scheme

In Dynamic Multi-Pathing (DMP), disk naming can be operating system-based naming or enclosure-based naming.

The following command displays whether the DMP disk-naming scheme is currently set. It also displays the attributes for the disk naming scheme, such as whether persistence is enabled.

To display the current disk-naming scheme and its mode of operations, use the following command:

See "Disk device naming in DMP" on page 24.

Regenerating persistent device names

The persistent device naming feature makes the names of disk devices persistent across system reboots. The Device Discovery Layer (DDL) assigns device names according to the persistent device name database.

If operating system-based naming is selected, each disk name is usually set to the name of one of the paths to the disk. After hardware reconfiguration and a subsequent reboot, the operating system may generate different names for the paths to the disks. Therefore, the persistent device names may no longer correspond to the actual paths. This does not prevent the disks from being used, but the association between the disk name and one of its paths is lost.

Similarly, if enclosure-based naming is selected, the device name depends on the name of the enclosure and an index number. If a hardware configuration changes the order of the LUNs exposed by the array, the persistent device name may not reflect the current index.

To regenerate persistent device names

To regenerate the persistent names repository, use the following command:

vxddladm [-c] assign names

The -c option clears all user-specified names and replaces them with autogenerated names.

If the -c option is not specified, existing user-specified names are maintained, but operating system-based and enclosure-based names are regenerated.

Changing device naming for enclosures controlled by third-party drivers

By default, enclosures controlled by third-party drivers (TPD) use pseudo device names based on the TPD-assigned node names. If you change the device naming to native, the devices are named in the same format as other Dynamic Multi-Pathing (DMP) devices. The devices use either operating system names (OSN) or enclosure-based names (EBN), depending on which naming scheme is set.

See "Displaying the disk-naming scheme" on page 168.

To change device naming for TPD-controlled enclosures

For disk enclosures that are controlled by third-party drivers (TPD) whose coexistence is supported by an appropriate Array Support Library (ASL), the default behavior is to assign device names that are based on the TPD-assigned node names. You can use the vxdmpadm command to switch between these names and the device names that are known to the operating system:

```
# vxdmpadm setattr enclosure enclosure_name tpdmode=native|pseudo
```

The argument to the tpdmode attribute selects names that are based on those used by the operating system (native), or TPD-assigned node names (pseudo).

The use of this command to change between TPD and operating system-based naming is illustrated in the following example for the enclosure named EMCO. In this example, the device-naming scheme is set to OSN.

vxdisk list

DEVICE	TYPE	DISK	GROUP	STATUS
emcpower10	auto:sliced	disk1	mydg	online
emcpower11	auto:sliced	disk2	mydg	online
emcpower12	auto:sliced	disk3	mydg	online
emcpower13	auto:sliced	disk4	mydg	online
emcpower14	auto:sliced	disk5	mydg	online
emcpower15	auto:sliced	disk6	mydg	online
emcpower16	auto:sliced	disk7	mydg	online
emcpower17	auto:sliced	disk8	mydg	online
emcpower18	auto:sliced	disk9	mydg	online
emcpower19	auto:sliced	disk10	mydg	online

vxdmpadm setattr enclosure EMC0 tpdmode=native

vxdisk list

```
Administering disks | 170 Discovering the association between enclosure-based disk names and OS-based disk names |
```

DEVICE	TYPE	DISK	GROUP	STATUS
hdisk1	auto:sliced	disk1	mydg	online
hdisk2	auto:sliced	disk2	mydg	online
hdisk3	auto:sliced	disk3	mydg	online
hdisk4	auto:sliced	disk4	mydg	online
hdisk5	auto:sliced	disk5	mydg	online
hdisk6	auto:sliced	disk6	mydg	online
hdisk7	auto:sliced	disk7	mydg	online
hdisk8	auto:sliced	disk8	mydg	online
hdisk9	auto:sliced	disk9	mydg	online
hdisk10	auto:sliced	disk10	mydg	online

If tpdmode is set to native, the path with the smallest device number is displayed.

Discovering the association between enclosure-based disk names and OS-based disk names

If you enable enclosure-based naming, the vxprint command displays the structure of a volume using enclosure-based disk device names (disk access names) rather than OS-based names.

To discover the association between enclosure-based disk names and OS-based disk names

 To discover the operating system-based names that are associated with a given enclosure-based disk name, use either of the following commands:

```
# vxdisk list enclosure-based_name
```

vxdmpadm getsubpaths dmpnodename=enclosure-based_name

For example, to find the physical device that is associated with disk ENC0_21, the appropriate commands would be:

```
# vxdisk list ENC0_21
# vxdmpadm getsubpaths dmpnodename=ENC0 21
```

To obtain the full pathname for the block disk device and the character disk device from these commands, append the displayed device name to /dev/vx/dmp/ or /dev/vx/rdmp/.

Chapter

Dynamic Reconfiguration of devices

This chapter includes the following topics:

- About online Dynamic Reconfiguration
- Reconfiguring a LUN online that is under DMP control
- Replacing a host bus adapter online
- Upgrading the array controller firmware online

About online Dynamic Reconfiguration

System administrators and storage administrators may need to modify the set of LUNs provisioned to a server. You can change the LUN configuration dynamically, without performing a reconfiguration reboot on the host.

You can perform the following kinds of online dynamic reconfigurations:

- Reconfiguring a LUN online that is under Dynamic Multi-Pathing (DMP) control See "Reconfiguring a LUN online that is under DMP control" on page 172.
- Replacing a host bus adapter (HBA) online
 See "Replacing a host bus adapter online" on page 177.
- Updating the array controller firmware, also known as a nondisruptive upgrade See "Upgrading the array controller firmware online" on page 177.

Reconfiguring a LUN online that is under DMP control

System administrators and storage administrators may need to modify the set of LUNs provisioned to a server. You can change the LUN configuration dynamically, without performing a reconfiguration reboot on the host.

The operations are as follows:

- Dynamic LUN removal from an existing target ID See "Removing LUNs dynamically from an existing target ID" on page 172.
- Dynamic new LUN addition to a new target ID
 See "Adding new LUNs dynamically to a target ID" on page 174.
- Replacing a LUN on an existing target ID See "Replacing LUNs dynamically from an existing target ID" on page 175.
- Changing the LUN characteristics
 See "Changing the characteristics of a LUN from the array side" on page 176.

Removing LUNs dynamically from an existing target ID

Dynamic Multi-Pathing (DMP) provides a Dynamic Reconfiguration tool to simplify the removal of LUNs from an existing target ID. Each LUN is unmapped from the host. DMP issues an operating system device scan and cleans up the operating system device tree.

Warning: Do not run any device discovery operations outside of the Dynamic Reconfiguration tool until the device operation is completed.

In a cluster, perform the steps on all nodes in the cluster.

To remove LUNs dynamically from an existing target ID

1 Stop all applications and volumes that are hosted on the LUNs that are to be removed.

For LUNs using AIX LVM over DMP devices, remove the device from the LVM volume group.

- # reducevg vgname pvname
- 2 Start the vxdiskadm utility:
 - # vxdiskadm

- 3 Select the Dynamic Reconfiguration operations option from the vxdiskadm menu.
- 4 Select the Remove LUNs option.
- **5** Type **list** or press **Return** to display a list of LUNs that are available for removal. A LUN is available for removal if it is not in use.

The following shows an example output:

```
Select disk devices to remove: [<pattern-list>,all,list]: list
LUN(s) available for removal:
eva4k6k0_0
eva4k6k0_1
eva4k6k0_2
eva4k6k0_3
eva4k6k0_4
emc0_017e
```

6 Enter the name of a LUN, a comma-separated list of LUNs, or a regular expression to specify the LUNs to remove.

For example, enter emc0 017e.

7 At the prompt, confirm the LUN selection.

DMP removes the LUN from VxVM usage.

8 At the following prompt, remove the LUN from the array/target.

```
Enclosure=emc0 AVID=017E

Device=emc0_017e Serial=830017E000

PATH=hdisk7 ctlr=c15 port=7e-a [50:01:43:80:12:08:3c:26]

PATH=hdisk8 ctlr=c17 port=7e-a [50:01:43:80:12:08:3a:76]

Please remove LUNs with above details from array and

press 'y' to continue removal (default:y):
```

9 Return to the Dynamic Reconfiguration tool and select $_{\mathbb{Y}}$ to continue the removal process.

DMP completes the removal of the device from VxVM usage. Output similar to the following displays:

```
Luns Removed
------
emc0_017e
```

DMP updates the operating system device tree and the VxVM device tree.

10 Select **exit** to exit the Dynamic Reconfiguration tool.

Adding new LUNs dynamically to a target ID

Dynamic Multi-Pathing (DMP) provides a Dynamic Reconfiguration tool to simplify the addition of new LUNs to a new or existing target ID. One or more new LUNs are mapped to the host by way of multiple HBA ports. An operating system device scan is issued for the LUNs to be recognized and added to DMP control.

Warning: Do not run any device discovery operations outside of the Dynamic Reconfiguration tool until the device operation is completed.

In a cluster, perform the steps on all the nodes in the cluster.

To add new LUNs dynamically to a target ID

- 1 Start the vxdiskadm utility:
 - # vxdiskadm
- 2 Select the Dynamic Reconfiguration operations option from the vxdiskadm menu.
- 3 Select the Add LUNs option.
- 4 When the prompt displays, add the LUNs from the array/target.

5 Select y to continue to add the LUNs to DMP.

DMP updates the operating system device tree and the VxVM device tree. The newly-discovered devices are now visible.

6 Select exit to exit the Dynamic Reconfiguration tool.

Replacing LUNs dynamically from an existing target ID

Dynamic Multi-Pathing (DMP) provides a Dynamic Reconfiguration tool to simplify the replacement of new LUNs from an existing target ID. Each LUN is unmapped from the host. DMP issues an operating system device scan and cleans up the operating system device tree.

Warning: Do not run any device discovery operations outside of the Dynamic Reconfiguration tool until the device operation is completed.

In a cluster, perform the steps on all the nodes in the cluster.

To replace LUNs dynamically from an existing target ID

1 Stop all applications and volumes that are hosted on the LUNs that are to be removed.

For LUNs using AIX LVM over DMP devices, remove the device from the LVM volume group.

- # reducevg vgname pvname
- 2 Start the vxdiskadm utility:
 - # vxdiskadm
- 3 Select the Dynamic Reconfiguration operations option from the vxdiskadm menu.

4 Select the Replace LUNs option.

The output displays a list of LUNs that are available for replacement. A LUN is available for replacement if there is no open on the LUN, and the state is online or nolabel.

- 5 Select one or more LUNs to replace.
- 6 At the prompt, confirm the LUN selection.
- 7 Remove the LUN from the array/target.
- 8 Return to the Dynamic Reconfiguration tool and select y to continue the removal.

After the removal completes successfully, the Dynamic Reconfiguration tool prompts you to add a LUN.

- **9** When the prompt displays, add the LUNs from the array/target.
- 10 Select y to continue to add the LUNs.

DMP updates the operating system device tree and the VxVM device tree. The newly-discovered devices are now visible.

Changing the characteristics of a LUN from the array side

Some arrays provide a way to change the properties of LUNs. In most cases, you must completely stop usage of the device before the device shows the changed characteristics. We recommend taking the device offline before changing the LUN properties, and bringing the device back online again afterwards.

In certain cases, such as EMC BCV and SRDF operations, the device can remain online during this procedure.

In a cluster, perform the steps on all the nodes in the cluster.

To change the properties of a LUN

1 Stop all applications and volumes that are hosted on the device.

If the device is in use by Veritas Volume Manager (VxVM), perform the following steps:

For LUNs using AIX LVM over DMP devices, remove the device from the LVM volume group or varyoff the volume group.

varyoffvg vgname

2 Change the LUN characteristics.

3 Bring the device online.

For a Veritas Volume Manager disk:

For LUNs using AIX LVM over DMP devices, add the device back into the LVM volume group or varyon the volume group.

varyonvg *vgnam*e

4 Use DMP to perform a device scan.

In a cluster, perform this command on all the nodes.

vxdisk scandisks

Replacing a host bus adapter online

Dynamic Multi-Pathing (DMP) provides a Dynamic Reconfiguration tool to simplify the removal of host bus adapters from an existing system.

To replace a host bus adapter online

1 Start the vxdiskadm utility:

vxdiskadm

- 2 Select the Dynamic Reconfiguration operations option from the vxdiskadm menu.
- 3 Select the Replace HBAs option.

The output displays a list of HBAs that are available to DMP.

- 4 Select one or more HBAs to replace.
- **5** At the prompt, confirm the HBA selection.
- 6 Replace the host bus adapter.
- 7 Return to the Dynamic Reconfiguration tool and select y to continue the replacement process.

DMP updates the operating system device tree.

Upgrading the array controller firmware online

Storage array subsystems need code upgrades as fixes, patches, or feature upgrades. You can perform these upgrades online when the file system is mounted and I/Os are being served to the storage.

Storage subsystems contain multiple controllers for redundancy. An online upgrade is done one controller at a time. Dynamic Multi-Pathing (DMP) fails over all I/O to an alternate controller while one of the controllers is undergoing an Online Controller Upgrade. After the controller has completely staged the code, it reboots, resets, and comes online with the new version of the code. The other controller goes through the same process, and I/O fails over to the alternate controller.

Note: Throughout this process, application I/O is not affected.

Array vendors have different names for this process. For example, EMC calls it a nondisruptive upgrade (NDU) for CLARiiON arrays.

A/A type arrays require no special handling during this online upgrade process. For A/P, A/PF, and ALUA type arrays, DMP performs array-specific handling through vendor-specific array policy modules (APMs) during an online controller code upgrade.

When a controller resets and reboots during a code upgrade, DMP detects this state through the SCSI status. DMP immediately fails over all I/O to the next controller.

If the array does not fully support NDU, all paths to the controllers may be unavailable for I/O for a short period of time. Before beginning the upgrade, set the dmp_lun_retry_timeout tunable to a period greater than the time that you expect the controllers to be unavailable for I/O. DMP does not fail the I/Os until the end of the dmp_lun_retry_timeout period, or until the I/O succeeds, whichever happens first. Therefore, you can perform the firmware upgrade without interrupting the application I/Os.

For example, if you expect the paths to be unavailable for I/O for 300 seconds, use the following command:

vxdmpadm settune dmp_lun_retry_timeout=300

DMP does not fail the I/Os for 300 seconds, or until the I/O succeeds.

To verify which arrays support Online Controller Upgrade or NDU, see the hardware compatibility list (HCL) at the following URL:

http://www.symantec.com/docs/TECH211575

Chapter

Event monitoring

This chapter includes the following topics:

- About the Dynamic Multi-Pathing (DMP) event source daemon (vxesd)
- Fabric Monitoring and proactive error detection
- Dynamic Multi-Pathing (DMP) discovery of iSCSI and SAN Fibre Channel topology
- DMP event logging
- Starting and stopping the Dynamic Multi-Pathing (DMP) event source daemon

About the Dynamic Multi-Pathing (DMP) event source daemon (vxesd)

The event source daemon (vxesd) is a Dynamic Multi-Pathing (DMP) component process that receives notifications of any device-related events that are used to take appropriate actions. The benefits of vxesd include:

- Monitoring of SAN fabric events and proactive error detection (SAN event) See "Fabric Monitoring and proactive error detection" on page 180.
- Logging of DMP events for troubleshooting (DMP event) See "DMP event logging" on page 181.
- Discovery of SAN components and HBA-array port connectivity (Fibre Channel and iSCSI)
 See "Dynamic Multi-Pathing (DMP) discovery of iSCSI and SAN Fibre Channel

topology" on page 181.

See "Starting and stopping the Dynamic Multi-Pathing (DMP) event source daemon" on page 182.

Fabric Monitoring and proactive error detection

DMP takes a proactive role in detecting errors on paths.

The DMP event source daemon vxesd uses the Storage Networking Industry Association (SNIA) HBA API library to receive SAN fabric events from the HBA.

DMP checks devices that are suspect based on the information from the SAN events, even if there is no active I/O. New I/O is directed to healthy paths while DMP verifies the suspect devices.

During startup, vxesd queries the HBA (by way of the SNIA library) to obtain the SAN topology. The vxesd daemon determines the Port World Wide Names (PWWN) that correspond to each of the device paths that are visible to the operating system. After the vxesd daemon obtains the topology, vxesd registers with the HBA for SAN event notification. If LUNs are disconnected from a SAN, the HBA notifies vxesd of the SAN event, specifying the PWWNs that are affected. The vxesd daemon uses this event information and correlates it with the previous topology information to determine which set of device paths have been affected.

The vxesd daemon sends the affected set to the vxconfigd daemon (DDL) so that the device paths can be marked as suspect.

When the path is marked as suspect, DMP does not send new I/O to the path unless it is the last path to the device. In the background, the DMP restore task checks the accessibility of the paths on its next periodic cycle using a SCSI inquiry probe. If the SCSI inquiry fails, DMP disables the path to the affected LUNs, which is also logged in the event log.

If the LUNs are reconnected at a later time, the HBA informs vxesd of the SAN event. When the DMP restore task runs its next test cycle, the disabled paths are checked with the SCSI probe and re-enabled if successful.

Note: If vxesd receives an HBA LINK UP event, the DMP restore task is restarted and the SCSI probes run immediately, without waiting for the next periodic cycle. When the DMP restore task is restarted, it starts a new periodic cycle. If the disabled paths are not accessible by the time of the first SCSI probe, they are re-tested on the next cycle (300s by default).

The fabric monitor functionality is disabled by default. The value of the dmp_monitor_fabric tunable is persistent across restarts.

To display the current value of the dmp_monitor_fabric tunable, use the following command:

vxdmpadm gettune dmp_monitor_fabric

To disable the Fabric Monitoring functionality, use the following command:

vxdmpadm settune dmp_monitor_fabric=off

To enable the Fabric Monitoring functionality, use the following command:

vxdmpadm settune dmp_monitor_fabric=on

Dynamic Multi-Pathing (DMP) discovery of iSCSI and SAN Fibre Channel topology

The vxesd builds a topology of iSCSI and Fibre Channel (FC) devices that are visible to the host. The vxesd daemon uses the SNIA Fibre Channel HBA API to obtain the SAN topology. If IMA is not available, then the iSCSI management CLI is used to obtain the iSCSI SAN topology.

To display the hierarchical listing of Fibre Channel and iSCSI devices, use the following command:

```
# vxddladm list
```

See the vxddladm(1M) manual page.

DMP event logging

See "About the Dynamic Multi-Pathing (DMP) event source daemon (vxesd)" on page 179.

The event source daemon (vxesd) is a Dynamic Multi-Pathing (DMP) component process that receives notifications of any device-related events that are used to take appropriate actions.

DMP notifies vxesd of major events, and vxesd logs the event in a log file. These events include:

- Marking paths or dmpnodes enabled
- Marking paths or dmpnodes disabled
- Throttling of paths
- I/O error analysis
- HBA and SAN events

You can change the level of detail that is displayed in the system or console log about the DMP events. Use the tunable dmp_log_level . Valid values are 1 through 9. The default level is 1.

```
# vxdmpadm settune dmp log level=X
```

The current value of dmp log level can be displayed with:

```
# vxdmpadm gettune dmp_log_level
```

For details on the various log levels, see the vxdmpadm(1M) manual page.

Starting and stopping the Dynamic Multi-Pathing (DMP) event source daemon

By default, Dynamic Multi-Pathing (DMP) starts the event source daemon, vxesd, at boot time.

To stop the vxesd daemon, use the vxddladm utility:

```
# vxddladm stop eventsource
```

To start the vxesd daemon, use the vxddladm utility:

```
# vxddladm start eventsource [logfile=logfilename]
```

To view the status of the vxesd daemon, use the vxddladm utility:

vxddladm status eventsource

Chapter

Performance monitoring and tuning

This chapter includes the following topics:

- About tuning Dynamic Multi-Pathing (DMP) with templates
- DMP tuning templates
- Example DMP tuning template
- Tuning a DMP host with a configuration attribute template
- Managing the DMP configuration files
- Resetting the DMP tunable parameters and attributes to the default values
- DMP tunable parameters and attributes that are supported for templates
- DMP tunable parameters
- DMP driver tunables

About tuning Dynamic Multi-Pathing (DMP) with templates

Dynamic Multi-Pathing has multiple tunable parameters and attributes that you can configure for optimal performance. DMP provides a template method to update several tunable parameters and attributes with a single operation. The template represents a full or partial DMP configuration, showing the values of the parameters and attributes of the host.

To view and work with the tunable parameters, you can dump the configuration values of the DMP tunable parameters to a file. Edit the parameters and attributes,

if required. Then, load the template file to a host to update all of the values in a single operation.

You can load the configuration file to the same host, or to another similar host. The template method is useful for the following scenarios:

- Configure multiple similar hosts with the optimal performance tuning values. Configure one host for optimal performance. After you have configured the host, dump the tunable parameters and attributes to a template file. You can then load the template file to another host with similar requirements. Symantec recommends that the hosts that use the same configuration template have the same operating system and similar I/O requirements.
- Define multiple specialized templates to handle different I/O load requirements. When the load changes on a host, you can load a different template for the best performance. This strategy is appropriate for predictable, temporary changes in the I/O load. As the system administrator, after you define the system's I/O load behavior, you can customize tuning templates for particular loads. You can then automate the tuning, since there is a single load command that you can use in scripts or cron jobs.

At any time, you can reset the configuration, which reverts the values of the tunable parameters and attributes to the DMP default values.

You can manage the DMP configuration file with the vxdmpadm config commands.

See the vxdmpadm(1m) man page.

DMP tuning templates

The template mechanism enables you to tune DMP parameters and attributes by dumping the configuration values to a file, or to standard output.

DMP supports tuning the following types of information with template files:

- DMP tunable parameters.
- DMP attributes defined for an enclosure, array name, or array type.
- Symantec naming scheme parameters.

The template file is divided into sections, as follows:

DMP Tunables	Applied to all enclosures and arrays.
Namingscheme	Applied to all enclosures and arrays.
Arraytype	Use to customize array types. Applied to all of the enclosures of the specified array type.

Arrayname	Use if particular arrays need customization; that is, if the tunables vary from those applied for the array type.
	Attributes in this section are applied to all of the enclosures of the specified array name.
Enclosurename	Applied to the enclosures of the specified Cab serial number and array name.
	Use if particular enclosures need customization; that is, if the tunables vary from those applied for the array type and array name.

Loading is atomic for the section. DMP loads each section only if all of the attributes in the section are valid. When all sections have been processed, DMP reports the list of errors and warns the user. DMP does not support a partial rollback. DMP verifies the tunables and attributes during the load process. However, Symantec recommends that you check the configuration template file before you attempt to load the file. Make any required corrections until the configuration file validates correctly.

The attributes are given priority in the following order when a template is loaded:

Enclosure Section > Array Name Section > Array Type Section

If all enclosures of the same array type need the same settings, then remove the corresponding array name and enclosure name sections from the template. Define the settings only in the array type section. If some of the enclosures or array names need customized settings, retain the attribute sections for the array names or enclosures. You can remove the entries for the enclosures or the array names if they use the same settings that are defined for the array type.

When you dump a configuration file from a host, that host may contain some arrays which are not visible on the other hosts. When you load the template to a target host that does not include the enclosure, array type, or array name, DMP ignores the sections.

You may not want to apply settings to non-shared arrays or some host-specific arrays on the target hosts. Be sure to define an enclosure section for each of those arrays in the template. When you load the template file to the target host, the enclosure section determines the settings. Otherwise, DMP applies the settings from the respective array name or array type sections.

Example DMP tuning template

This section shows an example of a DMP tuning template.

DMP Tunables dmp cache open=on dmp daemon count=10 dmp delayq interval=15 dmp restore state=enabled dmp fast recovery=on dmp health time=60 dmp log level=1 dmp low impact probe=on dmp lun retry timeout=30 dmp path age=300 dmp pathswitch blks shift=9 dmp probe idle lun=on dmp probe threshold=5 dmp restore cycles=10 dmp restore interval=300 dmp restore policy=check disabled dmp retry count=5 dmp scsi timeout=30 dmp sfg threshold=1 dmp stat interval=1 dmp monitor ownership=on dmp monitor fabric=on dmp monitor osevent=off dmp native support=off Namingscheme namingscheme=ebn persistence=yes lowercase=yes use avid=yes Arraytype arraytype=CLR-A/PF iopolicy=minimumq partitionsize=512 recoveryoption=nothrottle recoveryoption=timebound iotimeout=300 redundancy=0 Arraytype

Tuning a DMP host with a configuration attribute template

You can use a template file to upload a series of changes to the DMP configuration to the same host or to another similar host.

Symantec recommends that you load the DMP template to a host that is similar to the host that was the source of the tunable values.

To configure DMP on a host with a template

1 Dump the contents of the current host configuration to a file.

vxdmpadm config dump file=filename

2 Edit the file to make any required changes to the tunable parameters in the template.

The target host may include non-shared arrays or host-specific arrays. To avoid updating these with settings from the array name or array type, define an enclosure section for each of those arrays in the template. When you load the template file to the target host, the enclosure section determines the settings. Otherwise, DMP applies the settings from the respective array name or array type sections.

3 Validate the values of the DMP tunable parameters.

vxdmpadm config check file=filename

DMP displays no output if the configuration check is successful. If the file contains errors, DMP displays the errors. Make any required corrections until the configuration file is valid. For example, you may see errors such as the following:

```
VxVM vxdmpadm ERROR V-5-1-0 Template file 'error.file' contains
following errors:
Line No: 22 'dmp_daemon_count' can not be set to 0 or less
Line No: 44 Specified value for 'dmp_health_time' contains
non-digits
Line No: 64 Specified value for 'dmp_path_age' is beyond
the limit of its value
Line No: 76 'dmp_probe_idle_lun' can be set to either on or off
Line No: 281 Unknown arraytype
```

4 Load the file to the target host.

vxdmpadm config load file=filename

During the loading process, DMP validates each section of the template. DMP loads all valid sections. DMP does not load any section that contains errors.

Managing the DMP configuration files

You can display the name of the template file most recently loaded to the host. The information includes the date and time when DMP loaded the template file.

To display the name of the template file that the host currently uses

vxdmpadm config show

TEMPLATE_FILE	DATE		TIME
/tmp/myconfig	Feb 0	9, 2011	11:28:59

Resetting the DMP tunable parameters and attributes to the default values

DMP maintains the default values for the DMP tunable parameters and attributes. At any time, you can restore the default values to the host. Any changes that you applied to the host with template files are discarded.

To reset the DMP tunables to the default values

- Use the following command:
 - # vxdmpadm config reset

DMP tunable parameters and attributes that are supported for templates

DMP supports tuning the following tunable parameters and attributes with a configuration template.

DMP tunable parameters

See "DMP tunable parameters" on page 191.

DMP attributes defined for an enclosure, array
iopolicy name, or array type.

- partitionsize
- use_all_paths
- recoveryoption attributes (retrycount or iotimeout)
- redundancy
- dmp lun retry timeout

Naming scheme attributes:

- naming scheme
- persistence
- lowercase
- use_avid

The following tunable parameters are NOT supported with templates:

- OS tunables
- TPD mode
- Failover attributes of enclosures (failovermode)

DMP tunable parameters

DMP provides various parameters that you can use to tune your environment.

Table 8-1 shows the DMP parameters that can be tuned. You can set a tunable parameter online, without a reboot.

Parameter	Description
dmp_cache_open	If this parameter is set to on, the first open of a device is cached. This caching enhances the performance of device discovery by minimizing the overhead that is caused by subsequent opens on the device. If this parameter is set to off, caching is not performed. The default value is on.
dmp_daemon_count	The number of kernel threads that are available for servicing path error handling, path restoration, and other DMP administrative tasks.
	The default number of threads is 10.
dmp_delayq_interval	How long DMP should wait before retrying I/O after an array fails over to a standby path. Some disk arrays are not capable of accepting I/O requests immediately after failover.
	The default value is 15 seconds.

 Table 8-1
 DMP parameters that are tunable

Parameter	Description
dmp_fast_recovery	Whether DMP should try to obtain SCSI error information directly from the HBA interface. Setting the value to on can potentially provide faster error recovery, if the HBA interface supports the error enquir feature. If this parameter is set to off, the HBA interface is not used.
	The default setting is on.
dmp_health_time	DMP detects intermittently failing paths, and prevent I/O requests from being sent on them. The value of dmp_health_time represents the time in seconds for which a path must stay healthy. If a path's state changes back from enabled to disabled within this time period, DMP marks the path as intermittently failing, and does not re-enable the path for I/O until dmp_path_age seconds elapse.
	The default value is 60 seconds.
	A value of 0 prevents DMP from detecting intermittent failing paths.
dmp_log_level	The level of detail that is displayed for DMP console messages. The following level values are defined:
	1 — Displays all DMP log messages that are critical
	 2 — Displays level 1 messages plus messages that relate to path or disk addition or removal, SCSI errors IO errors and DMP node migration.
	3 — Displays level 1 and 2 messages plus message that relate to path throttling, suspect path, idle path an insane path logic.
	4 — Displays level 1, 2 and 3 messages plus message that relate to setting or changing attributes on a path and tunable related changes.
	5 or higher — Displays level 1, 2, 3 and 4 messages plus more verbose messages.
	The default value is 1.

 Table 8-1
 DMP parameters that are tunable (continued)

Parameter	Description
dmp_low_impact_probe	Determines if the path probing by restore daemon is optimized or not. Set it to $\circ n$ to enable optimization and $\circ ff$ to disable. Path probing is optimized only when restore policy is check_disabled or during check_disabled phase of check_periodic policy.
	The default value is on.
dmp_lun_retry_timeout	Specifies a retry period for handling transient errors that are not handled by the HBA and the SCSI driver.
	Specify the time in seconds.
	In general, no such special handling is required. Therefore, the default value of the dmp_lun_retry_timeout tunable parameter is 30. When all paths to a disk fail, DMP fails the I/Os to the application. The paths are checked for connectivity only once.
	In special cases when DMP needs to handle the transient errors, configure DMP to delay failing the I/Os to the application for a short interval. Set the dmp_lun_retry_timeout tunable parameter to a non-zero value to specify the interval. If all of the paths to the LUN fail and I/Os need to be serviced, then DMP probes the paths every five seconds for the specified interval. If the paths are restored within the interval, DMP detects this and retries the I/Os. DMP does not fail I/Os to a disk with all failed paths until the specified dmp_lun_retry_timeout interval or until the I/O succeeds on one of the paths, whichever happens first.
dmp_monitor_fabric	Determines if DMP should register for HBA events from SNIA HAB APIs. These events improve the failover performance by proactively avoiding the I/O paths that have impending failure.
	The default setting is off. Symantec recommends that this setting remain off to avoid performance issues on the AIX platform.

 Table 8-1
 DMP parameters that are tunable (continued)

Parameter	Description
dmp_monitor_ownership	Determines whether the ownership monitoring is enabled for ALUA arrays. When this tunable is set to on, DMP polls the devices for LUN ownership changes. The polling interval is specified by the dmp_restore_interval tunable. The default value is on.
	When the dmp_monitor_ownership tunable is off, DMP does not poll the devices for LUN ownership changes.
dmp_native_support	Determines whether DMP will do multi-pathing for native devices.
	Set the tunable to on to have DMP do multi-pathing for native devices.
	When Dynamic Multi-Pathing is installed as a component of another Veritas InfoScale product, the default value is off.
	When Dynamic Multi-Pathing is installed as a stand-alone product, the default value is on.
dmp_path_age	The time for which an intermittently failing path needs to be monitored as healthy before DMP again tries to schedule I/O requests on it.
	The default value is 300 seconds.
	A value of 0 prevents DMP from detecting intermittently failing paths.

 Table 8-1
 DMP parameters that are tunable (continued)

Parameter	Description
dmp_pathswitch_blks_shift	The default number of contiguous I/O blocks that are sent along a DMP path to an array before switching to the next available path. The value is expressed as the integer exponent of a power of 2; for example 9 represents 512 blocks.
	The default value is 9. In this case, 512 blocks (256k) of contiguous I/O are sent over a DMP path before switching. For intelligent disk arrays with internal data caches, better throughput may be obtained by increasing the value of this tunable. For example, for the HDS 9960 A/A array, the optimal value is between 15 and 17 for an I/O activity pattern that consists mostly of sequential reads or writes.
	This parameter only affects the behavior of the balanced I/O policy. A value of 0 disables multi-pathing for the policy unless the vxdmpadm command is used to specify a different partition size for an array.
	See "Specifying the I/O policy" on page 131.
dmp_probe_idle_lun	If DMP statistics gathering is enabled, set this tunable to on (default) to have the DMP path restoration thread probe idle LUNs. Set this tunable to off to turn off this feature. (Idle LUNs are VM disks on which no I/O requests are scheduled.) The value of this tunable is only interpreted when DMP statistics gathering is enabled. Turning off statistics gathering also disables idle LUN probing.
	The default value is on.
dmp_probe_threshold	If the dmp_low_impact_probe is turned on, dmp_probe_threshold determines the number of paths to probe before deciding on changing the state of othe paths in the same subpath failover group.

 Table 8-1
 DMP parameters that are tunable (continued)

Parameter	Description
dmp_restore_cycles	If the DMP restore policy is check_periodic, the number of cycles after which the check_all policy is called.
	The default value is 10.
	See "Configuring DMP path restoration policies" on page 145.
dmp_restore_interval	The interval attribute specifies how often the path restoration thread examines the paths. Specify the tim in seconds.
	The default value is 300.
	The value of this tunable can also be set using the vxdmpadm start restore command.
	See "Configuring DMP path restoration policies" on page 145.
dmp_restore_policy	The DMP restore policy, which can be set to one of the following values:
	• check_all
	 check_alternate
	check_disabled
	<pre>check_periodic</pre>
	The default value is check_disabled
	The value of this tunable can also be set using the vxdmpadm start restore command.
	See "Configuring DMP path restoration policies" on page 145.

 Table 8-1
 DMP parameters that are tunable (continued)

Parameter	Description
dmp_restore_state	If this parameter is set to enabled, it enables the path restoration thread to be started.
	See "Configuring DMP path restoration policies" on page 145.
	If this parameter is set to disabled, it stops and disables the path restoration thread.
	If this parameter is set to stopped, it stops the path restoration thread until the next device discovery cycle
	The default is enabled.
	See "Stopping the DMP path restoration thread" on page 146.
dmp_scsi_timeout	Determines the timeout value to be set for any SCSI command that is sent via DMP. If the HBA does not receive a response for a SCSI command that it has sent to the device within the timeout period, the SCS command is returned with a failure error code.
	The default value is 30 seconds.
dmp_sfg_threshold	Determines the minimum number of paths that should be failed in a failover group before DMP starts suspecting other paths in the same failover group. The value of 0 disables the failover logic based on subpath failover groups.
	The default value is 1.
dmp_stat_interval	The time interval between gathering DMP statistics.
	The default and minimum value are 1 second.

 Table 8-1
 DMP parameters that are tunable (continued)

DMP driver tunables

DMP uses a slab allocator to service I/Os. DMP uses the DMP driver tunables dmpslab_minsz and dmpslab_maxsz to control the memory allocated for this slab allocator. These tunables are defined as follows:

dmpslab_maxsz	Maximum size of the slab. The size is specified in pages, where 1 page equals 4096 bytes.
	The default value for dmpslab_maxsz is 5% of the physical memory.
dmpslab_minsz	The minimum memory size that should be allocated to the slab during the driver load time. The size is specified in pages, where 1 page equals 4096 bytes.
	The default value for dmpslab_minsz is 48 pages.

To display the tunables, use the following command:

```
# lsattr -El vxdmp
dmpslab_maxsz 101580 N/A True
dmpslab_minsz 48 N/A True
```

Note: If the errpt displays ENOMEM error code, you might need to change the dmpslab_minsz and dmpslab_maxsz to suit the load on the system.

Changing the value of the DMP driver tunables

Specify a new size in pages. You must increase the size in multiples of 8.
 To change the dmpslab minsz tunable:

chdev -P -1 vxdmp -a dmpslab_minsz=newsize

To change the dmpslab_maxsz tunable:

chdev -P -1 vxdmp -a dmpslab_maxsz=newsize

2 Reboot the system for the new values to take effect.

Appendix

DMP troubleshooting

This appendix includes the following topics:

- Displaying extended attributes after upgrading to DMP 7.0
- Recovering from errors when you exclude or include paths to DMP
- Downgrading the array support

Displaying extended attributes after upgrading to DMP 7.0

You may see the following changes in functionality when you upgrade to DMP 7.0 from the Storage Foundation 5.1 release:

- The device names that are listed in the vxdisk list output do not display the Array Volume IDs (AVIDs).
- The vxdisk -e list output does not display extended attributes.
- An Active/Passive (A/P) or ALUA array is claimed as Active/Active (A/A).

This behavior may be because the LUNs are controlled by the native multi-pathing driver, MPIO. When a LUN is controlled by TPD drivers like MPIO, then in DMP those enclosures are claimed as A/A (irrespective of what array mode LUN has at array). This is because multi-pathing is done from the TPD driver and DMP only sees oruses the TPD metanode to route commands. For TPD, DMP also suppresses the value-add extended attributes like AVID, media_type, and so on. If you migrate LUN multi-pathing to DMP, those extended attributes start showing with actual the LUN array mode as per the Array Support Library (ASL).

To check whether LUNs are controlled by native multi-pathing driver

• Check the output of the following command to see if the LUN is an MPIO device:

lsdev -Cc disk

You can migrate the LUNs from the control of the native multi-pathing driver to DMP control.

- To migrate to DMP with Veritas Volume Manager, refer to the section on disabling MPIO in the *Storage Foundation Administrator's Guide*.
- To migrate to DMP with OS native volume support, refer to the section on migrating to DMP from MPIO in the Dynamic Multi-Pathing Adminstrator's Guide.

Recovering from errors when you exclude or include paths to DMP

You can exclude a path from DMP with the vxdmpadm exclude command. You can return a previously excluded path to DMP control with the vxdmpadm include command. These commands use the vxvm.exclude file to store the excluded paths. The include path and exclude path operations cannot complete successfully if the vxvm.exclude file is corrupted.

The following error displays if the vxvm.exclude file is corrupted:

```
# vxdmpadm exclude ctlr=fscsi3
VxVM vxdmpadm ERROR V-5-1-3996 File not in correct format
```

DMP saves the corrupted file with the name vxvm.exclude.corrupt. DMP creates a new vxvm.exclude file. You must manually recover from this situation.

To recover from a corrupted exclude file

1 Reissue the vxdmpadm include command or the vxdmpadm exclude command that displayed the error.

```
# vxdmpadm exclude ctlr=fscsi3
```

2 View the saved vxvm.exclude.corrupt file to find any entries for the excluded paths that are relevant.

```
# cat /etc/vx/vxvm.exclude
```

```
exclude_all 0
paths
#
controllers
fscsi3 46-T1-01_3
#
product
#
pathgroups
#
```

3 Reissue the vxdmpadm exclude command for the paths that you noted in step 2.

```
# vxdmpadm exclude ctlr=c4
```

4 Verify that the excluded paths are in the vxvm.exclude file.

```
# cat /etc/vx/vxvm.exclude
```

```
exclude_all 0
paths
#
controllers
fscsi3 46-T1-01_3
#
product
#
```

Downgrading the array support

The array support is available in a single fileset, VRTSaslapm, that includes Array Support Libraries (ASLs) and Array Policy Modules (APMs). Each major release of Dynamic Multi-Pathing includes the supported VRTSaslapm fileset, which is installed as part of the product installation. Between major releases, Symantec may provide additional array support through updates to the VRTSaslapm fileset.

If you have issues with an updated VRTSaslapm fileset, Symantec may recommend that you downgrade to a previous version of the ASL/APM fileset. You can only revert to a fileset that is supported for the installed release of Dynamic Multi-Pathing. To perform the downgrade while the system is online, do not remove the installed fileset. Instead, you can install the previous version of the fileset over the new fileset. This method prevents multiple instances of the VRTSaslapm fileset from being installed.

Use the following method to downgrade the VRTSaslapm fileset.

To downgrade the ASL/APM fileset while online

- Specify the previous version of the VRTSaslapm fileset to the following command:
 - # installp -F -ad ./VRTSaslapm.bff VRTSaslapm

Appendix

Reference

This appendix includes the following topics:

Command completion for Veritas commands

Command completion for Veritas commands

Dynamic Multi-Pathing supports command completion for Dynamic Multi-Pathing (DMP) commands.

In this release, command completion is supported only on the bash shell. The shell must be bash version 2.4 or later.

To use this feature, press **Tab** while entering a supported VxVM or DMP command. The command is completed as far as possible. When there is a choice, the command completion displays the next valid options for the command. Enter one of the displayed values. A value in brackets indicates a user-specified value.

Note: Platform-specific options are not supported with command completion.

By default, you can use the command completion feature by invoking the bash shell on every log in. If you want to permanently enable the command completion, use the following command:

vxdctl cmdcompletion enable

The enable command completion creates the .bash profile file, if it is not present.

To permanently disable the command completion, use the following command:

vxdctl cmdcompletion disable

See the vxdctl(1M) manual page.

The following commands support command completion:

- vxddladm
- vxdisk
- vxdmpadm

Glossary

Active/Active disk arrays	This type of multi-pathed disk array allows you to access a disk in the disk array through all the paths to the disk simultaneously, without any performance degradation.
Active/Passive disk arrays	This type of multipathed disk array allows one path to a disk to be designated as primary and used to access the disk at any time. Using a path other than the designated active path results in severe performance degradation in some disk arrays.
associate	The process of establishing a relationship between VxVM objects; for example, a subdisk that has been created and defined as having a starting point within a plex is referred to as being associated with that plex.
associated plex	A plex associated with a volume.
associated subdisk	A subdisk associated with a plex.
attached	A state in which a VxVM object is both associated with another object and enabled for use.
block	The minimum unit of data transfer to or from a disk or array.
bootdg	A reserved disk group name that is an alias for the name of the boot disk group.
clean node shutdown	The ability of a node to leave a cluster gracefully when all access to shared volumes has ceased.
cluster	A set of hosts (each termed a node) that share a set of disks.
cluster manager	An externally-provided daemon that runs on each node in a cluster. The cluster managers on each node communicate with each other and inform VxVM of changes in cluster membership.
cluster-shareable disk group	A disk group in which access to the disks is shared by multiple hosts (also referred to as a shared disk group).
column	A set of one or more subdisks within a striped plex. Striping is achieved by allocating data alternately and evenly across the columns within a plex.
concatenation	A layout style characterized by subdisks that are arranged sequentially and contiguously.
configuration copy	A single copy of a configuration database.

configuration database	A set of records containing detailed information on existing VxVM objects (such as disk and volume attributes).
DCO (data change object)	A VxVM object that is used to manage information about the FastResync maps in the DCO volume. Both a DCO object and a DCO volume must be associated with a volume to implement Persistent FastResync on that volume.
data stripe	This represents the usable data portion of a stripe and is equal to the stripe minus the parity region.
DCO volume	A special volume that is used to hold Persistent FastResync change maps and dirty region logs. See also see dirty region logging.
detached	A state in which a VxVM object is associated with another object, but not enabled for use.
device name	The device name or address used to access a physical disk, such as $\tt hdisk3$, which indicates the whole of disk 3.
	In a SAN environment, it is more convenient to use enclosure-based naming, which forms the device name by concatenating the name of the enclosure (such as $enc0$) with the disk's number within the enclosure, separated by an underscore (for example, $enc0_2$). The term disk access name can also be used to refer to a device name.
dirty region logging	The method by which the VxVM monitors and logs modifications to a plex as a bitmap of changed regions. For a volumes with a new-style DCO volume, the dirty region log (DRL) is maintained in the DCO volume. Otherwise, the DRL is allocated to an associated subdisk called a log subdisk.
disabled path	A path to a disk that is not available for I/O. A path can be disabled due to real hardware failures or if the user has used the $vxdmpadm$ disable command on that controller.
disk	A collection of read/write data blocks that are indexed and can be accessed fairly quickly. Each disk has a universally unique identifier.
disk access name	An alternative term for a device name.
disk access records	Configuration records used to specify the access path to particular disks. Each disk access record contains a name, a type, and possibly some type-specific information, which is used by VxVM in deciding how to access and manipulate the disk that is defined by the disk access record.
disk array	A collection of disks logically arranged into an object. Arrays tend to provide benefits such as redundancy or improved performance.
disk array serial number	This is the serial number of the disk array. It is usually printed on the disk array cabinet or can be obtained by issuing a vendor- specific SCSI command to the

	disks on the disk array. This number is used by the DMP subsystem to uniquely identify a disk array.
disk controller	In the multi-pathing subsystem of VxVM, the controller (host bus adapter or HBA) or disk array connected to the host, which the operating system represents as the parent node of a disk.
disk enclosure	An intelligent disk array that usually has a backplane with a built-in Fibre Channel loop, and which permits hot-swapping of disks.
disk group	A collection of disks that share a common configuration. A disk group configuration is a set of records containing detailed information on existing VxVM objects (such as disk and volume attributes) and their relationships. Each disk group has an administrator-assigned name and an internally defined unique ID. The disk group names bootdg (an alias for the boot disk group), defaultdg (an alias for the default disk group) and nodg (represents no disk group) are reserved.
disk group ID	A unique identifier used to identify a disk group.
disk ID	A universally unique identifier that is given to each disk and can be used to identify the disk, even if it is moved.
disk media name	An alternative term for a disk name.
disk media record	A configuration record that identifies a particular disk, by disk ID, and gives that disk a logical (or administrative) name.
disk name	A logical or administrative name chosen for a disk that is under the control of VxVM, such as disk03. The term disk media name is also used to refer to a disk name.
dissociate	The process by which any link that exists between two VxVM objects is removed. For example, dissociating a subdisk from a plex removes the subdisk from the plex and adds the subdisk to the free space pool.
dissociated plex	A plex dissociated from a volume.
dissociated subdisk	A subdisk dissociated from a plex.
distributed lock manager	A lock manager that runs on different systems in a cluster, and ensures consistent access to distributed resources.
enabled path	A path to a disk that is available for I/O.
encapsulation	A process that converts existing partitions on a specified disk to volumes.
	Encapsulation is not supported on the AIX platform.
enclosure	See disk enclosure.
enclosure-based naming	See device name.

fabric mode disk	A disk device that is accessible on a Storage Area Network (SAN) via a Fibre Channel switch.
FastResync	A fast resynchronization feature that is used to perform quick and efficient resynchronization of stale mirrors, and to increase the efficiency of the snapshot mechanism.
Fibre Channel	A collective name for the fiber optic technology that is commonly used to set up a Storage Area Network (SAN).
file system	The organization of files on storage devices. The term file system can refer either to the entire file system or to a subsection of that file system, contained within a disk section or a logical volume that can be mounted or unmounted from that tree.
free subdisk	A subdisk that is not associated with any plex and has an empty ${\tt putil[0]}$ field.
hostid	A string that identifies a host to VxVM. The host ID for a host is stored in its volboot file, and is used in defining ownership of disks and disk groups.
hot-relocation	A technique of automatically restoring redundancy and access to mirrored and RAID-5 volumes when a disk fails. This is done by relocating the affected subdisks to disks designated as spares and/or free space in the same disk group.
hot-swap	Refers to devices that can be removed from, or inserted into, a system without first turning off the power supply to the system.
initiating node	The node on which the system administrator is running a utility that requests a change to VxVM objects. This node initiates a volume reconfiguration.
JBOD (just a bunch of	The common name for an unintelligent disk array which may, or may not, support
disks)	the hot-swapping of disks.
-	
disks)	the hot-swapping of disks. A plex used to store a RAID-5 log. The term log plex may also be used to refer to
disks) log plex	the hot-swapping of disks. A plex used to store a RAID-5 log. The term log plex may also be used to refer to a Dirty Region Logging plex.
disks) log plex log subdisk	the hot-swapping of disks.A plex used to store a RAID-5 log. The term log plex may also be used to refer to a Dirty Region Logging plex.A subdisk that is used to store a dirty region log.A node that is designated by the software to coordinate certain VxVM operations
disks) log plex log subdisk master node	the hot-swapping of disks.A plex used to store a RAID-5 log. The term log plex may also be used to refer to a Dirty Region Logging plex.A subdisk that is used to store a dirty region log.A node that is designated by the software to coordinate certain VxVM operations in a cluster. Any node is capable of being the master node.
disks) log plex log subdisk master node mastering node	 the hot-swapping of disks. A plex used to store a RAID-5 log. The term log plex may also be used to refer to a Dirty Region Logging plex. A subdisk that is used to store a dirty region log. A node that is designated by the software to coordinate certain VxVM operations in a cluster. Any node is capable of being the master node. The node to which a disk is attached. This is also known as a disk owner. A duplicate copy of a volume and the data therein (in the form of an ordered collection of subdisks). Each mirror consists of one plex of the volume with which

	DMP driver) that hides this fact from the user is said to provide multi-pathing functionality.
node	One of the hosts in a cluster.
node abort	A situation where a node leaves a cluster (on an emergency basis) without attempting to stop ongoing operations.
node join	The process through which a node joins a cluster and gains access to shared disks.
Non-Persistent FastResync	A form of FastResync that cannot preserve its maps across reboots of the system because it stores its change map in memory.
object	An entity that is defined to and recognized internally by VxVM. The VxVM objects are: volume, plex, subdisk, disk, and disk group. There are actually two types of disk objects—one for the physical aspect of the disk and the other for the logical aspect.
parity	A calculated value that can be used to reconstruct data after a failure. While data is being written to a RAID-5 volume, parity is also calculated by performing an exclusive OR (XOR) procedure on data. The resulting parity is then written to the volume. If a portion of a RAID-5 volume fails, the data that was on that portion of the failed volume can be recreated from the remaining data and the parity.
parity stripe unit	A RAID-5 volume storage region that contains parity information. The data contained in the parity stripe unit can be used to help reconstruct regions of a RAID-5 volume that are missing because of I/O or disk failures.
partition	The standard division of a physical disk device, as supported directly by the operating system and disk drives.
path	When a disk is connected to a host, the path to the disk consists of the HBA (Host Bus Adapter) on the host, the SCSI or fibre cable connector and the controller on the disk or disk array. These components constitute a path to a disk. A failure on any of these results in DMP trying to shift all I/O for that disk onto the remaining (alternate) paths.
pathgroup	In the case of disks which are not multipathed by vxdmp, VxVM will see each path as a disk. In such cases, all paths to the disk can be grouped. This way only one of the paths from the group is made visible to VxVM.
Persistent FastResync	A form of FastResync that can preserve its maps across reboots of the system by storing its change map in a DCO volume on disk).
persistent state logging	A logging type that ensures that only active mirrors are used for recovery purposes and prevents failed mirrors from being selected for recovery. This is also known as kernel logging.
physical disk	The underlying storage device, which may or may not be under VxVM control.

plex	A plex is a logical grouping of subdisks that creates an area of disk space independent of physical disk size or other restrictions. Mirroring is set up by creating multiple data plexes for a single volume. Each data plex in a mirrored volume contains an identical copy of the volume data. Plexes may also be created to represent concatenated, striped and RAID-5 volume layouts, and to store volume logs.
primary path	In Active/Passive disk arrays, a disk can be bound to one particular controller on the disk array or owned by a controller. The disk can then be accessed using the path through this particular controller.
private disk group	A disk group in which the disks are accessed by only one specific host in a cluster.
private region	A region of a physical disk used to store private, structured VxVM information. The private region contains a disk header, a table of contents, and a configuration database. The table of contents maps the contents of the disk. The disk header contains a disk ID. All data in the private region is duplicated for extra reliability.
public region	A region of a physical disk managed by VxVM that contains available space and is used for allocating subdisks.
RAID (redundant array of independent disks)	A disk array set up with part of the combined storage capacity used for storing duplicate information about the data stored in that array. This makes it possible to regenerate the data if a disk failure occurs.
read-writeback mode	A recovery mode in which each read operation recovers plex consistency for the region covered by the read. Plex consistency is recovered by reading data from blocks of one plex and writing the data to all other writable plexes.
root configuration	The configuration database for the root disk group. This is special in that it always contains records for other disk groups, which are used for backup purposes only. It also contains disk records that define all disk devices on the system.
root disk	The disk containing the root file system. This disk may be under VxVM control.
root file system	The initial file system mounted as part of the UNIX kernel startup sequence.
root partition	The disk region on which the root file system resides.
root volume	The VxVM volume that contains the root file system, if such a volume is designated by the system configuration.
rootability	The ability to place the $root$ file system and the $swap$ device under VxVM control. The resulting volumes can then be mirrored to provide redundancy and allow recovery in the event of disk failure.
	Rootability is not supported on the AIX platform.
secondary path	In Active/Passive disk arrays, the paths to a disk other than the primary path are called secondary paths. A disk is supposed to be accessed only through the primary

	path until it fails, after which ownership of the disk is transferred to one of the secondary paths.
sector	A unit of size, which can vary between systems. Sector size is set per device (hard drive, CD-ROM, and so on). Although all devices within a system are usually configured to the same sector size for interoperability, this is not always the case.
	A sector is commonly 512 bytes.
shared VM disk	A VM disk that belongs to a shared disk group in a cluster.
sparse plex	A plex that is not as long as the volume or that has holes (regions of the plex that do not have a backing subdisk).
SAN (storage area network)	A networking paradigm that provides easily reconfigurable connectivity between any subset of computers, disk storage and interconnecting hardware such as switches, hubs and bridges.
stripe size	The sum of the stripe unit sizes comprising a single stripe across all columns being striped.
striping	A layout technique that spreads data across several physical disks using stripes. The data is allocated alternately to the stripes within the subdisks of each plex.
swap area	A disk region used to hold copies of memory pages swapped out by the system pager process.
swap volume	A VxVM volume that is configured for use as a swap area.
transaction	A set of configuration changes that succeed or fail as a group, rather than individually. Transactions are used internally to maintain consistent configurations.
VM disk	A disk that is both under VxVM control and assigned to a disk group. VM disks are sometimes referred to as VxVM disks.
volboot file	A small file that is used to locate copies of the boot disk group configuration. The file may list disks that contain configuration copies in standard locations, and can also contain direct pointers to configuration copy locations. The <code>volboot</code> file is stored in a system-dependent location.
volume	A virtual disk, representing an addressable range of disk blocks used by applications such as file systems or databases. A volume is a collection of from one to 32 plexes.
volume configuration device	The volume configuration device ($/dev/vx/config$) is the interface through which all configuration changes to the volume device driver are performed.
volume device driver	The driver that forms the virtual disk drive between the application and the physical device driver level. The volume device driver is accessed through a virtual disk device node whose character device nodes appear in $/dev/vx/rdsk$, and whose block device nodes appear in $/dev/vx/dsk$.

vxconfigd The VxVM configuration daemon, which is responsible for making changes to the VxVM configuration. This daemon must be running before VxVM operations can be performed.
