Veritas™ Cluster Server
Administrator’s Guide

Windows Server 2003,
Windows Server 2008

5.1 Service Pack 1
Technical Support

Symantec Technical Support maintains support centers globally. Technical Support's primary role is to respond to specific queries about product features and functionality. The Technical Support group also creates content for our online Knowledge Base. The Technical Support group works collaboratively with the other functional areas within Symantec to answer your questions in a timely fashion. For example, the Technical Support group works with Product Engineering and Symantec Security Response to provide alerting services and virus definition updates.

Symantec's maintenance offerings include the following:

■ A range of support options that give you the flexibility to select the right amount of service for any size organization
■ Telephone and Web-based support that provides rapid response and up-to-the-minute information
■ Upgrade assurance that delivers automatic software upgrade protection
■ Global support that is available 24 hours a day, 7 days a week
■ Advanced features, including Account Management Services

For information about Symantec's Maintenance Programs, you can visit our Web site at the following URL:

http://www.symantec.com/business/support/index.jsp

Contacting Technical Support

Customers with a current maintenance agreement may access Technical Support information at the following URL:

http://www.symantec.com/business/support/contact_techsupp_static.jsp

Before contacting Technical Support, make sure you have satisfied the system requirements that are listed in your product documentation. Also, you should be at the computer on which the problem occurred, in case it is necessary to replicate the problem.

When you contact Technical Support, please have the following information available:

■ Product release level
■ Hardware information
■ Available memory, disk space, and NIC information
■ Operating system
■ Version and patch level
■ Network topology
■ Router, gateway, and IP address information
■ Problem description:
Error messages and log files
Troubleshooting that was performed before contacting Symantec
Recent software configuration changes and network changes

Licensing and registration
If your Symantec product requires registration or a license key, access our technical support Web page at the following URL:
http://customercare.symantec.com

Customer service
Customer service information is available at the following URL:
http://customercare.symantec.com
Customer Service is available to assist with the following types of issues:
- Questions regarding product licensing or serialization
- Product registration updates, such as address or name changes
- General product information (features, language availability, local dealers)
- Latest information about product updates and upgrades
- Information about upgrade assurance and maintenance contracts
- Information about the Symantec Buying Programs
- Advice about Symantec’s technical support options
- Nontechnical presales questions
- Issues that are related to CD-ROMs or manuals

Maintenance agreement resources
If you want to contact Symantec regarding an existing maintenance agreement, please contact the maintenance agreement administration team for your region as follows:

Asia-Pacific and Japan               customercare_apac@symantec.com
Europe, Middle-East, and Africa      semea@symantec.com
North America and Latin America     supportsolutions@symantec.com

Additional enterprise services
Symantec offers a comprehensive set of services that allow you to maximize your investment in Symantec products and to develop your knowledge, expertise, and global insight, which enable you to manage your business risks proactively.
Enterprise services that are available include the following:

**Symantec Early Warning Solutions**  These solutions provide early warning of cyber attacks, comprehensive threat analysis, and countermeasures to prevent attacks before they occur.

**Managed Security Services**  These services remove the burden of managing and monitoring security devices and events, ensuring rapid response to real threats.

**Consulting Services**  Symantec Consulting Services provide on-site technical expertise from Symantec and its trusted partners. Symantec Consulting Services offer a variety of prepackaged and customizable options that include assessment, design, implementation, monitoring, and management capabilities. Each is focused on establishing and maintaining the integrity and availability of your IT resources.

**Educational Services**  Educational Services provide a full array of technical training, security education, security certification, and awareness communication programs.

To access more information about Enterprise services, please visit our Web site at the following URL:

www.symantec.com

Introducing Veritas Cluster Server

■ What is a VCS cluster?
■ Can my application be clustered?
■ Physical components of VCS
■ Logical components of VCS
■ Putting the pieces together
What is a VCS cluster?

Veritas Cluster Server (VCS) from Symantec connects multiple, independent systems into a management framework for increased availability. Each system, or node, runs its own operating system and cooperates at the software level to form a cluster. VCS links commodity hardware with intelligent software to provide application failover and control. When a node or a monitored application fails, other nodes can take predefined actions to take over and bring up services elsewhere in the cluster.

How VCS detects failure

VCS detects failure of an application by issuing specific commands, tests, or scripts to monitor the overall health of an application. VCS also determines the health of underlying resources supporting the application, such as file systems and network interfaces.

VCS uses a redundant network heartbeat to discriminate between the loss of a system and the loss of communication between systems. VCS also uses membership coordination and data protection for detecting failure on a node and on fencing.

See “About cluster control, communications, and membership” on page 29.

How VCS ensures application availability

When VCS detects an application or node failure, VCS brings application services up on a different node in a cluster. VCS virtualizes IP addresses and system names, so client systems continue to access the application and are unaware of which server they use.
For example, in a 2-node cluster consisting of db-server1 and db-server2, a virtual address may be called db-server. Clients access db-server and are unaware of which physical server hosts the db-server.

**About switchover and failover**

Switchover and failover are the processes of bringing up application services on a different node in a cluster.

<table>
<thead>
<tr>
<th>Switchover</th>
<th>A switchover is an orderly shutdown of an application and its supporting resources on one server and a controlled startup on another server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failover</td>
<td>A failover is similar to a switchover, except the ordered shutdown of applications on the original node may not be possible, so the services are started on another node.</td>
</tr>
</tbody>
</table>
Can my application be clustered?

Most applications can be placed under cluster control provided the following guidelines are met:

- Defined start, stop, and monitor procedures.
- Ability to restart in a known state.
- Ability to store required data on shared disks.
- Adherence to license requirements and host name dependencies.

Defined start, stop, and monitor procedures

The application to be clustered must have defined procedures for starting, stopping, and monitoring.

Start procedure  The application must have a command to start it and all resources it may require. VCS brings up the required resources in a specific order, then brings up the application using the defined start procedure.

For example, to start an Oracle database, VCS must know which Oracle utility to call, such as sqlplus. VCS must also know the Oracle user, instance ID, Oracle home directory, and the pfile.

Stop procedure  An individual instance of the application must be capable of being stopped without affecting other instances.

For example, killing all HTTPd processes on a Web server is unacceptable because it would also stop other Web servers.

If VCS cannot stop an application cleanly, it may call for a more forceful method, like a kill signal. After a forced stop, a clean-up procedure may be required for various process- and application-specific items that may be left behind. These items include shared memory segments or semaphores.

Monitor procedure  The application must have a monitor procedure that determines if the specified application instance is healthy. The application must allow individual monitoring of unique instances.

For example, the monitor procedure for a Web server connects to the specified server and verifies that it is serving Web pages. In a database environment, the monitoring application can connect to the database server and perform SQL commands to verify read and write access to the database.

The closer a test comes to matching what a user does, the better the test is in discovering problems. You should balance the level of monitoring between ensuring that the application is up and minimizing monitor overhead.
Introducing Veritas Cluster Server

Can my application be clustered?

Ability to restart the application in a known state

When the application is taken offline, it must close out all tasks, store data properly on shared disk, and exit. Stateful servers must not keep that state of clients in memory. States should be written to shared storage to ensure proper failover.

Commercial databases such as Oracle, Sybase, or SQL Server are good examples of well-written, crash-tolerant applications. On any client SQL request, the client is responsible for holding the request until it receives acknowledgement from the server. When the server receives a request, it is placed in a special redo log file. The database confirms that the data is saved before it sends an acknowledgement to the client. After a server crashes, the database recovers to the last-known committed state by mounting the data tables and applying the redo logs. This returns the database to the time of the crash. The client resubmits any outstanding client requests that are unacknowledged by the server, and all others are contained in the redo logs.

If an application cannot recover gracefully after a server crashes, it cannot run in a cluster environment. The takeover server cannot start up because of data corruption and other problems.

External data storage

The application must be capable of storing all required data and configuration information on shared disks. The exception to this rule is a true shared nothing cluster.

See “Shared nothing cluster” on page 47.

For example, SQLServer 2000 can be set up so that the binaries are installed on the local system. The shared database and configuration information reside on a shared disk.

The application must also store data to disk rather than maintaining it in memory. The takeover system must be capable of accessing all required information. This requirement precludes the use of anything inside a single system inaccessible by the peer. NVRAM accelerator boards and other disk caching mechanisms for performance are acceptable, but must be done on the external array and not on the local host.
Licensing and host name issues

The application must be capable of running on all servers that are designated as potential hosts. This requirement means strict adherence to licensing requirements and host name dependencies. Changing host names can lead to significant management issues when multiple systems have the same host name after an outage. Custom scripting to modify a system host name on failover is not recommended. Symantec recommends you configure applications and licensing to run properly on all hosts.

Physical components of VCS

A VCS cluster comprises of systems that are connected with a dedicated communications infrastructure. VCS refers to a system that is part of a cluster as a node.

Each cluster has a unique cluster ID. Redundant cluster communication links connect systems in a cluster.

Nodes

VCS nodes host the service groups (managed applications). Each system is connected to networking hardware, and usually also to storage hardware. The systems contain components to provide resilient management of the applications, and start and stop agents.

Nodes can be individual systems, or they can be created with domains or partitions on enterprise-class systems. Individual cluster nodes each run their own operating system and possess their own boot device. Each node must run the same operating system within a single VCS cluster.

Clusters can have from 1 to 32 nodes. Applications can be configured to run on specific nodes within the cluster.

Shared storage

Storage is a key resource of most applications services, and therefore most service groups. A managed application can only be started on a system that has access to its associated data files. Therefore, a service group can only run on all systems in the cluster if the storage is shared across all systems. In many configurations, a storage area network (SAN) provides this requirement.

See "About cluster topologies" on page 37.
Introducing Veritas Cluster Server

Logical components of VCS

VCS is comprised of several components that provide the infrastructure to cluster an application.

Networking

Networking in the cluster is used for the following purposes:

- Communications between the cluster nodes and the customer systems.
- Communications between the cluster nodes.

Resources and resource dependencies

Resources are hardware or software entities that make up the application. Resources include disk groups and file systems, network interface cards (NIC), IP addresses, and applications.

Resource dependencies indicate resources that depend on each other because of application or operating system requirements. Resource dependencies are graphically depicted in a hierarchy, also called a tree, where the resources higher up (parent) depend on the resources lower down (child).

Figure 1-1 shows the hierarchy for a database application.

Figure 1-1  Sample resource dependency graph

Resource dependencies determine the order in which resources are brought online or taken offline. For example, a disk group must be imported before volumes in the disk group start, and volumes must start before file systems are
mounted. Conversely, file systems must be unmounted before volumes stop, and volumes must stop before disk groups are deported.

A parent is brought online after each child is brought online, and so on up the tree, until finally the application is started. Conversely, to take a managed application offline, you stop resources beginning at the top of the hierarchy. In this example, the application is stopped first, followed by the database application. Next the IP address and file systems can be stopped concurrently. These resources do not have any resource dependency between them, and so on down the tree.

Child resources must be online before parent resources can be brought online. Parent resources must be taken offline before child resources can be taken offline. If resources do not have parent-child interdependencies, they can be brought online or taken offline concurrently.

Categories of resources

Different types of resources require different levels of control. In VCS there are three categories of resources:

- **On-Off.** VCS starts and stops On-Off resources as required. For example, VCS imports a disk group when required, and deports it when it is no longer needed.

- **On-Only.** VCS starts On-Only resources, but does not stop them. For example, in the case of the FileOnOnly resource, VCS creates the file. VCS does not delete the file if the service group is taken offline.

- **Persistent.** These resources cannot be brought online or taken offline. For example, a network interface card cannot be started or stopped, but it is required to configure an IP address. A Persistent resource has an operation value of None. VCS monitors Persistent resources to ensure their status and operation. Failure of a Persistent resource triggers a service group failover.

Resource types

VCS defines a resource type for each resource it manages. For example, the NIC resource type can be configured to manage network interface cards. Similarly, all IP addresses can be configured using the IP resource type.

VCS includes a set of predefined resources types. For each resource type, VCS has a corresponding agent, which provides the logic to control resources.

See "About agents in VCS" on page 27.
Service groups

A service group is a virtual container that contains all the hardware and software resources that are required to run the managed application. Service groups allow VCS to control all the hardware and software resources of the managed application as a single unit. When a failover occurs, resources do not fail over individually—the entire service group fails over. If there is more than one service group on a system, a group may fail over without affecting the others.

Figure 1-2 Typical database service group

A single node may host any number of service groups, each providing a discrete service to networked clients. If the server crashes, all service groups on that node must be failed over elsewhere.

Service groups can be dependent on each other. For example a finance application may be dependent on a database application. Because the managed application consists of all components that are required to provide the service, service group dependencies create more complex managed applications. When you use service group dependencies, the managed application is the entire dependency tree.

See “About service group dependencies” on page 518.
Types of service groups

VCS service groups fall in three main categories: failover, parallel, and hybrid.

Failover service groups
A failover service group runs on one system in the cluster at a time. Failover groups are used for most applications that do not support multiple systems to simultaneously access the application’s data.

Parallel service groups
A parallel service group runs simultaneously on more than one system in the cluster. A parallel service group is more complex than a failover group. Parallel service groups are appropriate for applications that manage multiple application instances running simultaneously without data corruption.

Hybrid service groups
A hybrid service group is for replicated data clusters and is a combination of the failover and parallel service groups. It behaves as a failover group within a system zone and a parallel group across system zones.

A hybrid service group cannot fail over across system zones. VCS allows a switch operation on a hybrid group only if both systems are within the same system zone. If there are no systems within a zone for failover, VCS invokes the nofailover trigger on the lowest numbered node. Hybrid service groups adhere to the same rules governing group dependencies as do parallel groups.

See "About service group dependencies" on page 518.
See "nofailover event trigger" on page 557.
About the ClusterService group

The ClusterService group is a special purpose service group, which contains resources that are required by VCS components. The group contains resources for:

- Cluster Management Console
- Notification
- Wide-area connector (WAC) process, which is used in global clusters

The ClusterService group can fail over to any node despite restrictions such as frozen. The ClusterService group is the first service group to come online and cannot be autodisabled. The group comes online on the first node that goes in the running state. The VCS engine discourages taking the group offline manually.

About agents in VCS

Agents are multi-threaded processes that provide the logic to manage resources. VCS has one agent per resource type. The agent monitors all resources of that type; for example, a single IP agent manages all IP resources.

When the agent is started, it obtains the necessary configuration information from VCS. It then periodically monitors the resources, and updates VCS with the resource status.

The action to bring a resource online or take it offline differs significantly for each resource type. For example, bringing a disk group online requires importing the disk group. But, bringing a database online requires starting the database manager process and issuing the appropriate startup commands.

VCS monitors resources when they are online and offline to ensure they are not started on systems on which they are not supposed to run. For this reason, VCS starts the agent for any resource that is configured to run on a system when the cluster is started. If no resources of a particular type are configured, the agent is not started. For example, if there are no Oracle resources in your configuration, the Oracle agent is not started on the system.

Certain agents can identify when an application has been intentionally shut down outside of VCS control.

For agents that support this functionality, if an administrator intentionally shuts down an application outside of VCS control, VCS does not treat it as a fault. VCS sets the service group state as offline or partial, depending on the state of other resources in the service group.

This feature allows administrators to stop applications without causing a failover.
Agent functions

Agents carry out specific functions on resources. The functions an agent performs are called entry points. For details on any of the following agent functions, see the Veritas Cluster Server Agent Developer’s Guide.

- **Online**—Brings a specific resource **ONLINE** from an **OFFLINE** state.
- **Offline**—Takes a resource from an **ONLINE** state to an **OFFLINE** state.
- **Monitor**—Tests the status of a resource to determine if the resource is online or offline. The function runs at the following times:
  - During initial node startup, to probe and determine status of all resources on the system.
  - After every online and offline operation.
  - Periodically, to verify that the resource remains in its correct state. Under normal circumstances, the monitor entry point is run every 60 seconds when a resource is online. The entry point is run every 300 seconds when a resource is expected to be offline.
- **Clean**—Cleans up after a resource fails to come online, fails to go offline, or fails while in an **ONLINE** state. The clean entry point is designed to clean up after an application. The function ensures that the host system is returned to a valid state. For example, the clean function may remove shared memory segments or IPC resources that are left behind by a database.
- **Action**—Performs actions that can be completed in a short time and which are outside the scope of traditional activities such as online and offline. Some agents have predefined action scripts that you can run by invoking the action function.
- **Info**—Retrieves specific information for an online resource. The retrieved information is stored in the resource attribute ResourceInfo. This function is invoked periodically by the agent framework when the resource type attribute InfoInterval is set to a non-zero value. The InfoInterval attribute indicates the period after which the info function must be invoked. For example, the Mount agent may use this function to indicate the space available on the file system.

Agent classifications

**Bundled agents**

Bundled agents are packaged with VCS. They include agents for Disk, Mount, IP, and various other resource types.

See the Veritas Cluster Server Bundled Agents Reference Guide.
Introducing Veritas Cluster Server

Logical components of VCS

Enterprise agents
Enterprise agents control third party applications and are licensed separately. These include agents for Oracle, Sybase, and DB2. Contact your sales representative for more information.

Custom agents
Custom agents are agents that customers or by Symantec consultants develop. Typically, agents are developed because the user requires control of an application that the current bundled or enterprise agents do not support. See the Veritas Cluster Server Agent Developer’s Guide.

About the VCS agent framework
The VCS agent framework is a set of common, predefined functions that are compiled into each agent. These functions include the ability to connect to the VCS engine (HAD) and to understand common configuration attributes. The agent framework frees the developer from developing functions for the cluster; the developer can instead focus on controlling a specific resource type. For more information on developing agents, see the Veritas Cluster Server Agent Developer’s Guide.

About cluster control, communications, and membership
Cluster communications ensure that VCS is continuously aware of the status of each system’s service groups and resources. They also enable VCS to recognize which systems are active members of the cluster, which have joined or left the cluster, and which have failed.

About the high availability daemon (HAD)
The VCS high availability daemon (HAD) runs on each system. Also known as the VCS engine, HAD is responsible for:
- building the running cluster configuration from the configuration files
- distributing the information when new nodes join the cluster
- responding to operator input
- taking corrective action when something fails.

The engine uses agents to monitor and manage resources. It collects information about resource states from the agents on the local system and forwards it to all cluster members.

The local engine also receives information from the other cluster members to update its view of the cluster. HAD operates as a replicated state machine (RSM).
The engine running on each node has a completely synchronized view of the resource status on each node. Each instance of HAD follows the same code path for corrective action, as required.

The RSM is maintained through the use of a purpose-built communications package. The communications package consists of the protocols Low Latency Transport (LLT) and Group Membership Services/Atomic Broadcast (GAB).

The hashadow process monitors HAD and restarts it when required.

About Group Membership Services/Atomic Broadcast (GAB)

The Group Membership Services/Atomic Broadcast protocol (GAB) is responsible for cluster membership and cluster communications.

- Cluster Membership
  GAB maintains cluster membership by receiving input on the status of the heartbeat from each node by LLT. When a system no longer receives heartbeats from a peer, it marks the peer as DOWN and excludes the peer from the cluster. In VCS, memberships are sets of systems participating in the cluster. VCS has the following types of membership:
  - A regular membership includes systems that communicate with each other across one or more network channels.
  - A jeopardy membership includes systems that have only one private communication link.
  - Daemon Down Node Alive (DDNA) is a condition in which the VCS high availability daemon (HAD) on a node fails, but the node is running. In a DDNA condition, VCS does not have information about the state of service groups on the node. So, VCS places all service groups that were online on the affected node in the autodisabled state. The service groups that were online on the node cannot fail over. Manual intervention is required to enable failover of autodisabled service groups. The administrator must release the resources running on the affected node, clear resource faults, and bring the service groups online on another node.

- Cluster Communications
  GAB’s second function is reliable cluster communications. GAB provides guaranteed delivery of point-to-point and broadcast messages to all nodes. The VCS engine uses a private IOCTL (provided by GAB) to tell GAB that it is alive.
Introducing Veritas Cluster Server

Logical components of VCS

About Low Latency Transport (LLT)

VCS uses private network communications between cluster nodes for cluster maintenance. The Low Latency Transport functions as a high-performance, low-latency replacement for the IP stack, and is used for all cluster communications. Symantec recommends two independent networks between all cluster nodes. These networks provide the required redundancy in the communication path and enable VCS to discriminate between a network failure and a system failure. LLT has two major functions.

- Traffic Distribution
  LLT distributes (load balances) internode communication across all available private network links. This distribution means that all cluster communications are evenly distributed across all private network links (maximum eight) for performance and fault resilience. If a link fails, traffic is redirected to the remaining links.

- Heartbeat
  LLT is responsible for sending and receiving heartbeat traffic over network links. The Group Membership Services function of GAB uses this heartbeat function to determine cluster membership.
About security services

VCS uses the Symantec Product Authentication Service to provide secure communication between cluster nodes and clients, including the Java and the Web consoles. VCS uses digital certificates for authentication and uses SSL to encrypt communication over the public network.

In secure mode:

- VCS uses platform-based authentication.
- VCS does not store user passwords.
- All VCS users are system and domain users and are configured using fully-qualified user names. For example, administrator@vcsdomain. VCS provides a single sign-on mechanism, so authenticated users need not sign on each time to connect to a cluster.

VCS requires a system in your enterprise to be configured as a root broker. Additionally, all nodes in the cluster must be configured as authentication brokers.

- A root broker serves as the main registration and certification authority; it has a self-signed certificate and can authenticate other brokers. The root broker may be a system in the cluster. Symantec recommends having a single root broker per domain, typically a datacenter, acting as root broker for all products using Symantec Product Authentication Services. The root broker is only used during initial creation of an authentication broker.

- Authentication brokers serve as intermediate registration and certification authorities. An authentication broker authenticates users, such as a login to the cluster, or services, such as daemons running on application nodes, but cannot authenticate other brokers. Authentication brokers have certificates that are signed by the root. Each node in VCS serves as an authentication broker.

Security credentials for the authentication broker must be obtained from the root broker.

For secure communication, VCS components acquire credentials from the authentication broker that is configured on the local system. The acquired certificate is used during authentication and is presented to clients for the SSL handshake.
VCS and its components specify the account name and the domain in the following format:

- **HAD Account**
  - name = `_HA_VCS_(systemname)`
  - domain = `HA_SERVICES@(fully_qualified_system_name)`

- **CmdServer**
  - name = `_CMDSERVER_VCS_(systemname)`
  - domain = `HA_SERVICES@(fully_qualified_system_name)`

- **Wide-area connector**
  - name = `_WAC_GCO_(systemname)`
  - domain = `HA_SERVICES@(fully_qualified_system_name)`

### Components for administering VCS

VCS provides the following components to administer clusters:

**Veritas Cluster Server Management Console**
A Web-based graphical user interface for monitoring and administering the cluster.

- Install VCS Management Console on cluster nodes to manage a single cluster.
  
  See “Administering the cluster from the Cluster Management Console” on page 105.

- Install VCS Management Console on a management server outside the cluster to manage multiple clusters.
  
  See the *Veritas Cluster Server Management Console Implementation Guide* for more information.

**Cluster Manager (Java console)**
A cross-platform Java-based graphical user interface that provides complete administration capabilities for your cluster. The console runs on any system inside or outside the cluster, on any operating system that supports Java.

See “Administering the cluster from Cluster Manager (Java console)” on page 161.

**VCS command line interface (CLI)**
The VCS command-line interface provides a comprehensive set of commands for managing and administering the cluster.

See “Administering the cluster from the command line” on page 259.
Putting the pieces together

In the following example, a two-node cluster shares directories to clients. Both nodes are connected to shared storage, which enables them access to the directories being shared. A single service group, “FileShare_Group,” is configured to fail over between System A and System B. The service group consists of various resources, each with a different resource type.

The VCS engine, HAD, reads the configuration file, determines what agents are required to control the resources in the service group, and starts the agents. HAD uses resource dependencies to determine the order in which to bring the resources online. VCS issues online commands to the corresponding agents in the correct order.

The following figure shows the dependency graph for the service group FileShare_Group.

In this configuration, HAD starts agents for the disk group, mount, share, NIC, and IP on all systems configured to run FileShare_Group.

The resource dependencies are configured as:

■ The MountV resource requires the VMDg resource to be online before it can be brought online. The FileShare resource requires the MountV resource to be online before it can be brought online.

■ The IP resource requires the NIC resource to be online before it can be brought online. The NIC resource is a persistent resource and does not need to be started.

■ The Lanman resource required the FileShare and IP resources to be online before it can be brought online.

The service group can be configured to start automatically on either node in the preceding example. It can then move or fail over to the second node on command or automatically if the first node fails. On failover or relocation, VCS
Introducing Veritas Cluster Server
Putting the pieces together

starts offline the resources beginning at the top of the graph and start them on the second node beginning at the bottom.
Putting the pieces together
About cluster topologies

- Basic failover configurations
- Advanced failover configurations
- Cluster topologies and storage configurations
Basic failover configurations

This section describes basic failover configurations, including asymmetric, symmetric, and N-to-1.

Asymmetric or Active/Passive configuration

In an asymmetric configuration, an application runs on a primary, or master, server. A dedicated redundant server is present to take over on any failure. The redundant server is not configured to perform any other functions. In the following illustration, a database application is moved, or failed over, from the master to the redundant server.

![Asymmetric failover diagram]

Figure 2-1  Asymmetric failover

This configuration is the simplest and most reliable. The redundant server is on stand-by with full performance capability. If other applications are running, they present no compatibility issues.
Symmetric or Active/Active configuration

In a symmetric configuration, each server is configured to run a specific application or service and provide redundancy for its peer. In this example, each server runs one application service group. When a failure occurs, the surviving server hosts both application groups.

Figure 2-2  Symmetric failover
Symmetric configurations appear more efficient in terms of hardware utilization. In the asymmetric example, the redundant server requires only as much processor power as its peer. On failover, performance remains the same. In the symmetric example, the redundant server requires adequate processor power to run the existing application and the new application it takes over.

Further issues can arise in symmetric configurations when multiple applications running on the same system do not co-exist properly. Some applications work well with multiple copies started on the same system, but others fail. Issues can also arise when two applications with different I/O and memory requirements run on the same system.
N-to-1 configuration

An N-to-1 failover configuration reduces the cost of hardware redundancy and still provides a potential, dedicated spare. In an asymmetric configuration there is no performance penalty. There are no issues with multiple applications running on the same system; however, the drawback is the 100 percent redundancy cost at the server level.

![N-to-1 configuration diagram](image)

**Figure 2-3** N-to-1 configuration

An N-to-1 configuration is based on the concept that multiple, simultaneous server failures are unlikely; therefore, a single redundant server can protect multiple active servers. When a server fails, its applications move to the redundant server. For example, in a 4-to-1 configuration, one server can protect four servers. This configuration reduces redundancy cost at the server level from 100 percent to 25 percent. In this configuration, a dedicated, redundant server is cabled to all storage and acts as a spare when a failure occurs.
The problem with this design is the issue of failback. When the failed server is repaired, all services that are hosted on the server must be failed back to the server. The failback action frees the spare server and restores redundancy to the cluster.

Figure 2-4  N-to-1 failover requiring failback
Most shortcomings of early N-to-1 cluster configurations were caused by the limitations of storage architecture. Typically, it was impossible to connect more than two hosts to a storage array without complex cabling schemes and their inherent reliability problems, or resorting to expensive arrays with multiple controller ports.
Advanced failover configurations

This section describes advanced failover configurations for VCS.

N + 1 configuration

With the capabilities introduced by storage area networks (SANs), you cannot only create larger clusters, but can connect multiple servers to the same storage.

Figure 2-5  N+1 configuration
A dedicated, redundant server is no longer required in the configuration. Instead of N-to-1 configurations, you can use an N+1 configuration. In advanced N+1 configurations, an extra server in the cluster is spare capacity only.
When a server fails, the application service group restarts on the spare. After the server is repaired, it becomes the spare. This configuration eliminates the need for a second application failure to fail back the service group to the primary system. Any server can provide redundancy to any other server.

**Figure 2-6**  
N+1 failover
N-to-N configuration

An N-to-N configuration refers to multiple service groups running on multiple servers, with each service group capable of being failed over to different servers. For example, consider a four-node cluster with each node supporting three critical database instances.

If any node fails, each instance is started on a different node, ensuring that no single node becomes overloaded. This configuration is a logical evolution of N + 1: it provides cluster *standby capacity* instead of a *standby server*.

N-to-N configurations require careful testing to ensure that all applications are compatible. Applications must also have complete control of where service groups fail when an event occurs.
Cluster topologies and storage configurations

This section describes commonly-used cluster topologies, along with the storage configuration used to support the topologies.

Basic shared storage cluster

In this configuration, a single cluster shares access to a storage device, typically over a SAN. An application can only be started on a node with access to the required storage. For example, in a multi-node cluster, any node that is designated to run a specific database instance must have access to the storage where the database’s tablespaces, redo logs and control files are stored. Shared disk architecture is also the easiest to implement and maintain. When a node or application fails, all data that is required to start on another node is stored on the shared disk.

Figure 2-8  Shared disk architecture for basic cluster
Campus, or Metropolitan, shared storage cluster

In a campus environment, VCS and Veritas Volume Manager are used to create a cluster that spans multiple datacenters or buildings. Instead of a single storage array, data is mirrored between arrays using Veritas Volume Manager. This configuration provides synchronized copies of data at both sites. This procedure is identical to mirroring between two arrays in a datacenter, only now it is spread over a distance.

Figure 2-9  Campus shared storage cluster

A campus cluster requires two independent network links for heartbeat, two storage arrays each providing highly available disks, and public network connectivity between buildings on same IP subnet. If the campus cluster setup resides on different subnets with one for each site, then use the VCS Lanman agent to handle the network changes or issue the DNS changes manually.
Shared nothing cluster

Systems in shared nothing clusters do not share access to disks; they maintain separate copies of data. VCS shared nothing clusters typically have read-only data stored locally on both systems. For example, a pair of systems in a cluster that includes a critical Web server, which provides access to a backend database. The Web server runs on local disks and does not require data sharing at the Web server level.

**Figure 2-10** Shared nothing cluster
Replicated data cluster

In a replicated data cluster there is no shared disk. Instead, a data replication product synchronizes copies of data between nodes. Replication can take place at the application, host, and storage levels. Application-level replication products, such as Oracle DataGuard, maintain consistent copies of data between systems at the SQL or database levels. Host-based replication products, such as Veritas Volume Replicator, maintain consistent storage at the logical volume level. Storage- or array-based replication maintains consistent copies of data at the disk or RAID LUN level.

The following illustration shows a hybrid shared storage/replicated data cluster, in which different failover priorities are assigned to nodes according to particular service groups.

Figure 2-11  Shared storage replicated data cluster

Replicated data clusters can also be configured without the ability to fail over locally, but this configuration is not recommended.
Global cluster

A global cluster links clusters at separate locations and enables wide-area failover and disaster recovery.

Local clustering provides local failover for each site or building. Campus and replicated cluster configurations offer protection against disasters affecting limited geographic regions. Large scale disasters such as major floods, hurricanes, and earthquakes can cause outages for an entire city or region. In such situations, you can ensure data availability by migrating applications to sites located considerable distances apart.

Figure 2-12   Global cluster

In a global cluster, if an application or a system fails, the application is migrated to another system within the same cluster. If the entire cluster fails, the application is migrated to a system in another cluster. Clustering on a global level also requires replicating shared data to the remote site.

See “How VCS global clusters work” on page 572.

Cluster topologies and storage configurations
VCS configuration concepts

- About configuring VCS
- About the VCS configuration language
- About the main.cf file
- The types.cf file
- About VCS attributes
- About VCS keywords and reserved words
- VCS environment variables
About configuring VCS

Configuring VCS means conveying to the VCS engine the definitions of the cluster, service groups, resources, and resource dependencies. VCS uses two configuration files in a default configuration:

- **main.cf**—Defines the cluster, including service groups and resources.
- **types.cf**—Defines the resource types.

By default, both files reside in the following directory:

```
%VCS_HOME%\conf\config
```

Additional files similar to `types.cf` may be present if agents have been added, such as `Oracletypes.cf`.

In a VCS cluster, the first system to be brought online reads the configuration file and creates an internal (in-memory) representation of the configuration. Systems brought online after the first system derive their information from systems running in the cluster.

You must stop the cluster while you are modifying the files from the command line. Changes made by editing the configuration files take effect when the cluster is restarted. The node on which the changes were made should be the first node to be brought back online.

About the VCS configuration language

The VCS configuration language specifies the makeup of service groups and their associated entities, such as resource types, resources, and attributes. These specifications are expressed in configuration files, whose names contain the suffix `.cf`.

There are several ways to generate configuration files:

- Use the web-based Cluster Management Console
- Use Cluster Manager (Java Console).
- Use the command-line interface.
- If VCS is not running, use a text editor to create and modify the files.
About the main.cf file

The format of the main.cf file comprises include clauses and definitions for the cluster, systems, service groups, and resources. The main.cf file also includes service group and resource dependency clauses.

- Include clauses—Include clauses incorporate additional configuration files into main.cf. These additional files typically contain type definitions, including the types.cf file. Typically, custom agents add type definitions in their own files.
  
  ```
  include "types.cf"
  
  “About including multiple .cf files in main.cf” on page 55.
  ```

- Cluster definition— Defines the attributes of the cluster, including the cluster name and the names of the cluster users.
  
  ```
  cluster demo (
  UserNames = { admin = cDRpdxPmHzpS }
  )
  ```
  See “Cluster attributes” on page 786.

- System definition—Lists the systems designated as part of the cluster. The system names must match the name returned by the command `uname -a`. Each service group can be configured to run on a subset of systems defined in this section.
  
  ```
  system Server1
  system Server2
  ```

- Service group definition—Service group definitions in main.cf comprise the attributes of a particular service group.
  
  ```
  group FileShare_Group (
  SystemList = { SystemA, SystemB }
  AutoStartList = { SystemA }
  )
  ```
  See “Service group attributes” on page 764.
  See “About the SystemList attribute” on page 54.

- Resource definition—Defines each resource used in a particular service group. Resources can be added in any order and the utility hacf arranges the resources alphabetically the first time the configuration file is run.
  
  ```
  NIC NIC_resource (
  MACAddress @ system1= "02-B0-D0-D1-88-0E"
  MACAddress @ system2= "50-B0-D0-D1-88-23"
  )
  ```

- Resource dependency clause—Defines a relationship between resources. A dependency is indicated by the keyword requires between two resource names.
  
  ```
  IP_resource requires NIC_resource
  ```
See “Resources and resource dependencies” on page 23.

- Service group dependency clause—To configure a service group dependency, place the keyword requires in the service group declaration of the main.cf file. Position the dependency clause before the resource dependency specifications and after the resource declarations.

```plaintext
group_x requires group_y
```

See “About service group dependencies” on page 518.

About the SystemList attribute

The SystemList attribute designates all systems on which a service group can come online. By default, the order of systems in the list defines the priority of systems used in a failover. For example, the following definition configures SystemA to be the first choice on failover, followed by SystemB and then SystemC.

```plaintext
SystemList = { SystemA, SystemB, SystemC}
```

System priority may also be assigned explicitly in the SystemList attribute by assigning numeric values to each system name. For example:

```plaintext
SystemList = {SystemA=0, SystemB=1, SystemC=2}
```

If you do not assign numeric priority values, VCS assigns a priority to the system without a number by adding 1 to the priority of the preceding system. For example, if the SystemList is defined as follows, VCS assigns the values SystemA = 0, SystemB = 2, SystemC = 3.

```plaintext
SystemList = {SystemA, SystemB=2, SystemC},
```

Note that a duplicate numeric priority value may be assigned in some situations:

```plaintext
SystemList = {SystemA, SystemB=0, SystemC}
```

The numeric values assigned are SystemA = 0, SystemB = 0, SystemC = 1.

To avoid this situation, do not assign any numbers or assign different numbers to each system in SystemList.

Initial configuration

When VCS is installed, a basic main.cf configuration file is created with the cluster name, systems in the cluster, and a Cluster Manager user named admin with the password password.

The following is an example of the main.cf for cluster demo and systems SystemA and SystemB.

```plaintext
include "types.cf"
cluster demo {
  UserNames = { admin = cDRpdxPmHzpS }
}
system SystemA
system SystemB
```
About including multiple .cf files in main.cf

You may choose to include several configuration files in the main.cf file. For example:

```bash
include "applicationtypes.cf"
include "listofsystems.cf"
include "applicationgroup.cf"
```

If you include other .cf files in main.cf, the following considerations apply:

- Resource type definitions must appear before the definitions of any groups that use the resource types.
  In the following example, the applicationgroup.cf file includes the service group definition for an application. The service group includes resources whose resource types are defined in the file applicationtypes.cf. In this situation, the applicationtypes.cf file must appear first in the main.cf file.
  For example:
  ```bash
  include "applicationtypes.cf"
  include "applicationgroup.cf"
  ```

- If you define heartbeats outside of the main.cf file and include the heartbeat definition file, saving the main.cf file results in the heartbeat definitions getting added directly to the main.cf file.

The types.cf file

The types.cf file describes standard resource types to the VCS engine; specifically, the data required to control a specific resource.

```bash
type IP {
  static i18nstr ArgList[] = { Address, SubNetMask, MACAddress
  str Address
  str SubNetMask
  str MACAddress
}
```

The types definition performs two important functions:

- Defines the type of values that may be set for each attribute.
  In the IP example, the Address attribute is classified as str, or string. See “Attribute data types” on page 57.

- Defines the parameters passed to the VCS engine through the ArgList attribute. The line static str ArgList[] = { xxx, yyy, zzz } defines the order in which parameters are passed to the agents for starting, stopping, and monitoring resources.
For another example, review the following main.cf and types.cf representing an IP resource:

**main.cf for Windows**

```
IP IP_resource {
    Address = "192.168.1.201"
    SubNetMask = "255.255.254.0"
    MACAddress @ system1= "02-B0-D5-D1-88-0E"
    MACAddress @ system2= "04-B0-D0-D1-88-43"
}
```

**types.cf for Windows**

```
type IP {
    static i18nstr ArgList[] = { Address, SubNetMask, MACAddress}
    str Address
    str SubNetMask
    str MACAddress
}
```

The high-availability address is configured on the interface defined by the Address attribute.

The IP address is enclosed in double quotes because the string contains periods. See "Attribute data types" on page 57.

The VCS engine passes the identical arguments to the IP agent for online, offline, clean and monitor. It is up to the agent to use the arguments it requires. All resource names must be unique in a VCS cluster.
About VCS attributes

VCS components are configured using attributes. Attributes contain data about the cluster, systems, service groups, resources, resource types, agent, and heartbeats if using global clusters. For example, the value of a service group’s SystemList attribute specifies on which systems the group is configured and the priority of each system within the group. Each attribute has a definition and a value. Attributes also have default values assigned when a value is not specified.

Attribute data types

VCS supports the following data types for attributes.

- **String**: A string is a sequence of characters enclosed by double quotes. A string may also contain double quotes, but the quotes must be immediately preceded by a backslash. A backslash is represented in a string as \\.

  Quotes are not required if a string begins with a letter, and contains only letters, numbers, dashes (-), and underscores (_). For example, a string defining a network interface such as hme0 or eth0 does not require quotes as it contains only letters and numbers. However a string defining an IP address contains periods and requires quotes, such as: 192.168.100.1

  VCS also supports UTF-8 encoded values for some attributes. See “Localizable attributes” on page 60.

- **Integer**: Signed integer constants are a sequence of digits from 0 to 9. They may be preceded by a dash, and are interpreted in base 10. Integers cannot exceed the value of a 32-bit signed integer: 2147483647.

- **Boolean**: A boolean is an integer, the possible values of which are 0 (false) and 1 (true).
### About VCS attributes

VCS attributes have the following dimensions.

**Scalar**
A scalar has only one value. This is the default dimension.

**Vector**
A vector is an ordered list of values. Each value is indexed using a positive integer beginning with zero. Use a comma (,) or a semi-colon (;) to separate values. A set of brackets ([[]]) after the attribute name denotes that the dimension is a vector.

For example, an agent's `ArgList` is defined as:
```cpp
static str ArgList[] = { Address, SubNetMask, MACAddress }
```

**Keylist**
A keylist is an unordered list of strings, and each string is unique within the list. Use a comma (,) or a semi-colon (;) to separate values.

For example, to designate the list of systems on which a service group will be started with VCS (usually at system boot):
```cpp
AutoStartList = (SystemA; SystemB; SystemC)
```

**Association**
An association is an unordered list of name-value pairs. Use a comma (,) or a semi-colon (;) to separate values.

A set of braces ({{}}) after the attribute name denotes that an attribute is an association.

For example, to designate the list of systems on which the service group is configured to run and the system's priorities:
```cpp
SystemList = {SystemA=1, SystemB=2, SystemC=3}
```
## Attributes and cluster objects

VCS has the following types of attributes, depending on the cluster object the attribute applies to.

<table>
<thead>
<tr>
<th>Cluster attributes</th>
<th>Attributes that define the cluster. For example, ClusterName and ClusterAddress.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service group attributes</td>
<td>Attributes that define a service group in the cluster. For example, Administrators and ClusterList.</td>
</tr>
<tr>
<td>System attributes</td>
<td>Attributes that define the system in the cluster. For example, Capacity and Limits.</td>
</tr>
<tr>
<td>Resource type attributes</td>
<td>Attributes that define the resource types in VCS. These can be further classified as:</td>
</tr>
<tr>
<td><img src="type-independent" alt="Type-independent" /></td>
<td>Attributes that all agents (or resource types) understand. Examples: RestartLimit and MonitorInterval; these can be set for any resource type. Typically, these attributes are set for all resources of a specific type. For example, setting MonitorInterval for the IP resource type affects all IP resources.</td>
</tr>
<tr>
<td><img src="type-dependent" alt="Type-dependent" /></td>
<td>Attributes that apply to a particular resource type. These attributes appear in the type definition file (types.cf) for the agent. Example: The Address attribute applies only to the IP resource type. Attributes defined in the file types.cf apply to all resources of a particular resource type. Defining these attributes in the main.cf file overrides the values in the types.cf file for a specific resource. For example, setting StartVolumes = 1 for the DiskGroup types.cf defaults StartVolumes to True for all DiskGroup resources. Setting the value in main.cf overrides the value on a per-resource basis.</td>
</tr>
<tr>
<td><img src="static" alt="Static" /></td>
<td>These attributes apply for every resource of a particular type. These attributes are prefixed with the term static and are not included in the resource's argument list. You can override some static attributes and assign them resource-specific values. See “Overriding resource type static attributes” on page 302.</td>
</tr>
<tr>
<td>Resource attributes</td>
<td>Attributes that define a specific resource. Some of these attributes are type-independent. For example, you can configure the Critical attribute for any resource. Some resource attributes are type-dependent. For example, the Address attribute defines the IP address associated with the IP resource. These attributes are defined in the main.cf file.</td>
</tr>
</tbody>
</table>
Localizable attributes

VCS supports UTF-8 encoded localized values for some attributes. These attributes are identified by the i18nstr keyword in the type definition file types.cf.

For example, in the FileOnOff agent, the attribute PathName is a localizable attribute.

```c
type FileOnOff {
    static i18nstr ArgList[] = { PathName }
    i18nstr PathName
}
```

You can add a localizable string attribute using the `haattr -add -i18nstring` command.

Attribute scope across systems: global and local attributes

An attribute whose value applies to all systems is global in scope. An attribute whose value applies on a per-system basis is local in scope. The `at` operator (@) indicates the system to which a local value applies.

An example of local attributes can be found in the IP resource type where Mac addresses and routing options are assigned per machine.

```c
IP IP_resource {
    Address = "192.168.1.201"
    SubNetMask = "255.255.254.0"
    MACAddress @ system1 = "02-B1-D5-D1-88-0E"
    MACAddress @ system2 = "04-B0-D0-D1-88-43"
}
```

Attribute life: temporary attributes

You can define temporary attributes in the types.cf file. The values of temporary attributes remain in memory as long as VCS is running. Values of temporary attributes are not available when the cluster is restarted. These attribute values are not stored in the main.cf file.

Temporary attributes cannot be converted to permanent, and vice-versa. When you save a configuration, VCS saves temporary attributes and their default values in the file types.cf.

The scope of these attributes can be local to a node or global across all nodes in the cluster. Local attributes can be defined even when the node is not part of a cluster.

You can define and modify these attributes only while VCS is running.

See “Adding, deleting, and modifying resource attributes” on page 294.
Size limitations for VCS objects

The following VCS objects are restricted to 1024 characters.
- Service group names
- Resource names
- Resource type names
- User names
- Attribute names

VCS passwords are restricted to 255 characters. You can enter a password of maximum 255 characters.

About VCS keywords and reserved words

The following list includes the current keywords reserved for the VCS configuration language. Note they are case-sensitive.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Keyword</th>
<th>Keyword</th>
<th>Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>false</td>
<td>local</td>
<td>requires</td>
</tr>

</table>
VCS environment variables

Table 3-1 lists VCS environment variables.

Table 3-1  VCS environment variables

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Definition and Default Value</th>
</tr>
</thead>
</table>
| PERL5LIB             | Root directory for Perl executables. (applicable only for Windows)  
**Default:** Install Drive:\Program Files\VERITAS\cluster server\lib\perl5. |
| VCS_CONF             | Root directory for VCS configuration files.  
**Default:** Install Drive:\Program Files\VERITAS\cluster server\conf\config |
|                      | **Note:** If this variable is added or modified you must reboot the system to apply the changes. |
| VCS_DOMAIN           | The Security domain in which users are configured. |
| VCS_DOMAINTYPE       | Type of domain: unixpwd, nt, nis, nisplus, or vx. |
| VCS_DIAG             | Directory where VCS dumps HAD cores. |
| VCS_ENABLE_LDF       | Designates whether or not log data files (LDFs) are generated. If set to a non-zero integer, LDFs are generated. If set to 0, they are not. |
| VCS_HOME             | Root directory for VCS executables.  
**Default:** Install Drive:\Program Files\VERITAS\cluster server\ |
| VCS_HOST             | VCS node on which ha commands will be run. |
| VCS_GAB_PORT         | GAB port to which VCS connects.  
**Default:** h |
| VCS_GAB_TIMEOUT      | Timeout in milliseconds for HAD to send heartbeats to GAB.  
**Default:** 30000 |
|                      | **Note:** If the specified timeout is exceeded, GAB kills HAD, and all active service groups on system are disabled. |
### VCS environment variables

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Definition and Default Value</th>
</tr>
</thead>
</table>
| **VCS_GAB_RMTIMEOUT** | Timeout in seconds for HAD to register with GAB.  
  **Default:** 200  
  See “Registration monitoring” on page 668. |
| **VCS_GAB_RMACTION** | Controls the GAB behavior when VCS_GAB_RMTIMEOUT exceeds.  
  You can set the value as follows:  
  ■ panic—GAB panics the system  
  ■ SYSLOG—GAB logs an appropriate message  
  **Default:** SYSLOG  
  See “Registration monitoring” on page 668. |
| **VCS_HAD_RESTART_TIMEOUT** | Set this variable to designate the amount of time the hashadow process waits (sleep time) before restarting HAD.  
  **Default:** 0 |
| **VCS_LOG** | Root directory for log files and temporary files.  
  **Default:** Install Drive:\Program Files\VERITAS\cluster server\  
  **Note:** If this variable is added or modified you must reboot the system to apply the changes. |
| **VCS_SERVICE** | Name of configured VCS service.  
  **Default:** vcs  
  **Note:** The specified service should be configured before starting the VCS engine (HAD). If a service is not specified, the VCS engine starts with port 14141. |
| **VCS_TEMP_DIR** | Directory in which temporary information required by, or generated by, hacf is stored.  
  **Default:** Install Drive:\Program Files\VERITAS\cluster server\  
  This directory is created in /tmp under the following conditions:  
  ■ The variable is not set.  
  ■ The variable is set but the directory to which it is set does not exist.  
  ■ The utility hacf cannot find the default location. |

- Chapter 5, “Getting started with VCS” on page 75
- Chapter 7, “Administering the cluster from Cluster Manager (Java console)” on page 161
- Chapter 8, “Administering the cluster from the command line” on page 259
- Chapter 9, “Configuring resources and applications in VCS” on page 305
- Chapter 10, “Modifying the cluster configuration” on page 421
- Chapter 11, “Predicting VCS behavior using VCS Simulator” on page 457
About the VCS user privilege model

- About VCS user privileges and roles
- How administrators assign roles to users
- User privileges for OS user groups for clusters running in secure mode
- About VCS privileges for users with multiple roles
About VCS user privileges and roles

Cluster operations are enabled or restricted depending on the privileges with which you log on. VCS has three privilege levels: Administrator, Operator, and Guest. VCS provides some predefined user roles; each role has specific privilege levels. For example, the role Guest has the fewest privileges, Cluster Administrator the most.

See “VCS user privileges—administration matrices” on page 729.

About VCS privilege levels

VCS privilege levels include:

- Administrators—Can perform all operations, including configuration options on the cluster, service groups, systems, resources, and users.
- Operators—Can perform specific operations on a cluster or a service group.
- Guests—Can view specified objects.

About user roles in VCS

Table 4-1 lists the predefined VCS user roles, with a summary of their associated privileges.

<table>
<thead>
<tr>
<th>User Role</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster Administrator</td>
<td>Cluster Administrators are assigned full privileges, including making configuration read-write, creating and deleting groups, setting group dependencies, adding and deleting systems, and adding, modifying, and deleting users. All group and resource operations are allowed. Users with Cluster Administrator privileges can also change other users’ privileges and passwords. To stop a cluster, cluster administrators require administrative privileges on the local system. <strong>Note:</strong> Cluster Administrators can change their own and other users’ passwords only after changing the configuration to read/write mode. Cluster Administrators can create and delete resource types.</td>
</tr>
</tbody>
</table>
### About VCS user privilege model

Cluster Operators can perform all cluster-, group-, and resource-level operations, including modifying the user’s own password, bringing service groups online and taking them offline.

**Note:** Cluster Operators can change their own passwords only if configuration is in read/write mode. Cluster Administrators can change the configuration to the read/write mode.

Users with this role can be assigned Group Administrator privileges for specific service groups.

Group Administrators can perform all service group operations on specific groups, such as bringing groups and resources online, taking them offline, and creating or deleting resources. Additionally, users can establish resource dependencies and freeze or unfreeze service groups.

**Note:** Group Administrators cannot create or delete service groups.

Group Operators can bring service groups and resources online and take them offline. Users can also temporarily freeze or unfreeze service groups.

Cluster Guests have read-only access to the cluster, meaning they can view the configuration, but cannot change it. They can modify their own passwords only if the configuration is in read/write mode. They cannot add or update users. Additionally, users with this privilege can be assigned Group Administrator or Group Operator privileges for specific service groups.

**Note:** By default, newly created users are assigned Cluster Guest permissions.

Group Guests have read-only access to the service group, meaning they can view the configuration, but cannot change it. The Group Guest role is available for clusters running in secure mode.

<table>
<thead>
<tr>
<th>User Role</th>
<th>Privileges</th>

Additionally, users with this privilege can be assigned Group Administrator or Group Operator privileges for specific service groups.  
**Note:** By default, newly created users are assigned Cluster Guest permissions. |
| Group Guest | Group Guests have read-only access to the service group, meaning they can view the configuration, but cannot change it. The Group Guest role is available for clusters running in secure mode. |
About the hierarchy in VCS roles

The following illustration shows the roles and how they overlap with one another.

For example, Cluster Administrator includes privileges for Group Administrator, which includes privileges for Group Operator

User privileges for CLI commands

Users logged with administrative or root privileges are granted privileges that exceed those of Cluster Administrator, such as the ability to start and stop a cluster.
User privileges in global clusters

VCS permits a cross-cluster online or offline operation only if the user initiating the operation has one of the following privileges:

- Group Administrator or Group Operator privileges for the group on the remote cluster
- Cluster Administrator or Cluster Operator privileges on the remote cluster

VCS permits a cross-cluster switch operation only if the user initiating the operation has the following privileges:

- Group Administrator or Group Operator privileges for the group on both clusters
- Cluster Administrator or Cluster Operator privileges on both clusters

User privileges for clusters running in secure mode

In secure mode, VCS assigns Guest privileges to all native users.

When assigning privileges for clusters running in secure mode, you must specify fully-qualified user names, in the format username@domain.

You cannot assign or change passwords for users using VCS when VCS is running in secure mode.

How administrators assign roles to users

To assign a role to a user, an administrator performs the following tasks:

- Add a user to the cluster, if the cluster is not running in secure mode.
- Assign a role to the user.
- Assign the user a set of objects appropriate for the role. For clusters running in secure mode, you can also add a role to an operating system user group. See “User privileges for OS user groups for clusters running in secure mode” on page 72.

For example, an administrator may assign a user the Group Administrator role for specific service groups. Now, the user has privileges to perform operations on the specific service groups.

You can manage users and their privileges from the command line or from the graphical user interface.

See "Managing VCS users from the command line" on page 277
See "Administering user profiles" on page 197.
User privileges for OS user groups for clusters running in secure mode

For clusters running in secure mode, you can assign privileges to native users individually or at an operating system (OS) user group level.

For example, you may decide that all users that are part of the OS Administrators group get administrative privileges to the cluster or to a specific service group. Assigning a VCS role to a user group assigns the same VCS privileges to all members of the user group, unless you specifically exclude individual users from those privileges.

When you add a user to an OS user group, the user inherits VCS privileges assigned to the user group.

Assigning VCS privileges to an OS user group involves adding the user group in one (or more) of the following attributes:

- AdministratorGroups—for a cluster or for a service group.
- OperatorGroups—for a cluster or for a service group.

For example, user Tom belongs to an OS user group: OSUserGroup1. You can assign VCS privileges to user Tom in the following ways:

<table>
<thead>
<tr>
<th>To assign privileges</th>
<th>At an individual level, configure attribute</th>
<th>To the OS user group, configure attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster Administrator</td>
<td>cluster (Administrators = {tom@domain})</td>
<td>cluster (AdministratorGroups = {OSUserGroup1@domain})</td>
</tr>
<tr>
<td>Cluster Operator</td>
<td>cluster (Operators = {tom@domain})</td>
<td>cluster (OperatorGroups = {OSUserGroup1@domain})</td>
</tr>
<tr>
<td>Cluster Guest</td>
<td>Cluster (Guests = {tom@domain})</td>
<td></td>
</tr>
<tr>
<td>Group Administrator</td>
<td>group group_name (Administrators = {tom@domain})</td>
<td>group group_name (AdministratorGroups = {OSUserGroup1@domain})</td>
</tr>
<tr>
<td>Group Operator</td>
<td>group group_name (Operators = {tom@domain})</td>
<td>group group_name (OperatorGroups = {OSUserGroup1@domain})</td>
</tr>
<tr>
<td>Group Guest</td>
<td>Cluster (Guests = {tom@domain})</td>
<td></td>
</tr>
</tbody>
</table>
# About VCS privileges for users with multiple roles

Table 4-2 describes how VCS assigns privileges to users with multiple roles. The scenarios describe user Tom who is part of two OS user groups: OSUserGroup1 and OSUserGroup2.

<table>
<thead>
<tr>
<th>Situation and rule</th>
<th>Roles assigned in the VCS configuration</th>
<th>Privileges that VCS grants Tom</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Situation</strong>: Multiple roles at an individual level. <strong>Rule</strong>: VCS grants highest privileges (or a union of all the privileges) to the user.</td>
<td>Tom: Cluster Administrator Tom: Group Operator</td>
<td>Cluster Administrator.</td>
</tr>
<tr>
<td><strong>Situation</strong>: Roles at an individual and OS user group level (secure clusters only). <strong>Rule</strong>: VCS gives precedence to the role granted at the individual level.</td>
<td>Tom: Group Operator OSUserGroup1: Cluster Administrator</td>
<td>Group Operator</td>
</tr>
<tr>
<td><strong>Situation</strong>: Different roles for different OS user groups (secure clusters only). <strong>Rule</strong>: VCS grants the highest privilege (or a union of all privileges of all user groups) to the user.</td>
<td>OSUserGroup1: Cluster Administrators OSUserGroup2: Cluster Operators</td>
<td>Cluster Administrator</td>
</tr>
<tr>
<td><strong>Situation</strong>: Roles at an individual and OS user group level (secure clusters only). <strong>Rule</strong>: VCS gives precedence to the role granted at the individual level. You can use this behavior to exclude specific users from inheriting VCS privileges assigned to their OS user groups.</td>
<td>OSUserGroup1: Cluster Administrators OSUserGroup2: Cluster Operators Tom: Group Operator</td>
<td>Group Operator</td>
</tr>
</tbody>
</table>
Getting started with VCS

■ About getting started with VCS
■ Configuring a cluster using the VCS Cluster Configuration Wizard
■ Configuring a cluster from the command line
■ Analyzing a domain
About getting started with VCS

This chapter provides information on setting up a cluster after installing VCS. For instructions on installing VCS, refer to one of the following documents:

- If you purchased VCS for Windows, refer to the *Veritas Cluster Server for Windows Installation and Upgrade Guide.*
- If you purchased Veritas Storage Foundation High Availability for Windows (SFW HA), refer to the *Veritas Storage Foundation and High Availability Solutions Installation and Upgrade Guide.*

The VCS Cluster Configuration Wizard (VCW) configures cluster components including LLT and GAB, the user account for the VCS Helper service, and the Symantec Product Authentication Service. The wizard also configures the ClusterService group, which contains resources for Cluster Management Console (Single Cluster Mode) also referred to as Web Console, notification, and inter-cluster communication for global clusters. The wizard also modifies and removes cluster configurations.

Prerequisites

- Verify VCS is installed on all systems. Note that VCS must be installed on servers in a Active Directory domain.
- Verify that each system can access the shared storage devices.
- Symantec recommends using three network adapters (two NICs exclusively for the private network and one for the public network). You can implement the second private link as a low-priority link over a public interface. Route each private NIC through a separate hub or switch to avoid single points of failure. Symantec recommends disabling TCP/IP from private NICs to lower system overhead.
- Verify the public adapters on each node use static IP addresses (DHCP is not supported) and that name resolution is configured for each node.
- Set the required privileges:
  - You must have administrator privileges on the system where you run the wizard. The user account must be a domain account.
  - You must have administrative access to all systems selected for cluster operations. Add the domain user to the Local Administrators group of each system.
  - If you plan to create a new user account for the VCS Helper service, you must have Domain Administrator privileges, or you must belong to the Domain Account Operators group.
When configuring a user account for the VCS Helper service, make sure that the user account is a domain user. The VCS HAD, which runs in the context of the local system built-in account, uses the VCS Helper Service user context to access the network. This account does not require domain admin privileges.

Make sure the VCS Helper Service domain user account has "Add workstations to domain" privilege enabled in the Active Directory.

Configuring a cluster using the VCS Cluster Configuration Wizard

This section provides instructions for setting up a new cluster. You can also modify an existing cluster using the VCS Cluster Configuration Wizard. See “Modifying the cluster configuration” on page 421.

To configure a VCS cluster
1. Start the VCS Cluster Configuration wizard.
   Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Cluster Configuration Wizard.
2. Read the information on the Welcome panel and click Next.
3. On the Configuration Options panel, click Cluster Operations and click Next.
4 On the Domain Selection panel, select or type the name of the domain in which the cluster resides and select the discovery options.

Do one of the following:

- To discover information about all systems and users in the domain:
  - Clear the Specify systems and users manually check box.
  - Click Next.
  
  Proceed to step 8 on page 79.

- To specify systems and user names manually (recommended for large domains):
  - Check the Specify systems and users manually check box.
    Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.
  - Click Next.
    If you chose to retrieve the list of systems, proceed to step 6 on page 79. Otherwise proceed to the next step.

5 On the System Selection panel, type the name of each system to be added, click Add, and then click Next.

Do not specify systems that are part of another cluster.

Proceed to step 8 on page 79.
6 On the System Selection panel, specify the systems to form a cluster and then click **Next**. Do not select systems that are part of another cluster.

Enter the name of the system and click **Add** to add the system to the Selected Systems list, or click to select the system in the Domain Systems list and then click the **>** (right-arrow) button.

7 The System Report panel displays the validation status, whether **Accepted** or **Rejected**, of all the systems you specified earlier. Review the status and then click **Next**.

A system can be rejected for any of the following reasons:

- System is not pingable.
- WMI access is disabled on the system.
- Wizard is unable to retrieve the system architecture or operating system.
- VCS is either not installed on the system or the version of VCS is different from what is installed on the system on which you are running the wizard.

Select a system to see the validation details. If you wish to include a rejected system, rectify the error based on the reason for rejection and then run the wizard again.

8 On the Cluster Configuration Options panel, click **Create New Cluster** and click **Next**.
9 On the Cluster Details panel, specify the details for the cluster and then click Next.

Cluster Name: Type a name for the new cluster. Symantec recommends a maximum length of 32 characters for the cluster name.

Cluster ID: Select a cluster ID from the suggested cluster IDs in the drop-down list, or type a unique ID for the cluster. The cluster ID can be any number from 0 to 255. **Caution:** If you chose to specify systems and users manually in step 4 or if you share a private network between more than one domain, make sure that the cluster ID is unique.

Operating System: From the drop-down list, select the operating system. The Available Systems box then displays all the systems that are running the specified operating system. All the systems in the cluster must have the same operating system and architecture. You cannot configure a 32-bit and a 64-bit system in the same cluster.
Getting started with VCS

Configuring a cluster using the VCS Cluster Configuration Wizard

The wizard validates the selected systems for cluster membership. After the systems are validated, click Next. If a system is not validated, review the message associated with the failure and restart the wizard after rectifying the problem. If you chose to configure a private link heartbeat in the earlier step, proceed to the next step. Otherwise, proceed to step 12 on page 83.

On the Private Network Configuration panel, configure the VCS private network and click Next. You can configure the VCS private network either over the ethernet or over the User Datagram Protocol (UDP) layer.

Do one of the following:

- To configure the VCS private network over ethernet, complete the following steps:

  Select the check boxes next to the two NICs to be assigned to the private network.

Available Systems

Select the systems that you wish to configure in the cluster. Check the Select all systems check box to select all the systems simultaneously.

The wizard discovers the NICs on the selected systems. For single-node clusters with the required number of NICs, the wizard prompts you to configure a private link heartbeat. In the dialog box, click Yes to configure a private link heartbeat.
Symantec recommends reserving two NICs exclusively for the private network. However, you could lower the priority of one NIC and use the low-priority NIC for both public and private communication.

- If you have only two NICs on a selected system, it is recommended that you lower the priority of at least one NIC that will be used for private as well as public network communication. To lower the priority of a NIC, right-click the NIC and select **Low Priority** from the pop-up menu.

- If your configuration contains teamed NICs, the wizard groups them as NIC Group #N where N is a number assigned to the teamed NIC. A teamed NIC is a logical NIC, formed by grouping several physical NICs together. All NICs in a team have an identical MAC address. Symantec recommends that you do not select teamed NICs for the private network.

The wizard configures the LLT service (over ethernet) on the selected network adapters.

- To configure the VCS private network over the User Datagram Protocol (UDP) layer, complete the following steps:

  - Check the **Configure LLT over UDP** check box.
  - Specify a unique UDP port in the **Port number for Link1** and **Port number for Link2** fields. You can use ports in the range 49152 to
83 Getting started with VCS

Configuring a cluster using the VCS Cluster Configuration Wizard

65535. The default ports numbers are 50000 and 50001 respectively.

- Select the check boxes next to the two NICs to be assigned to the private network. Symantec recommends reserving two NICs exclusively for the VCS private network.

- For each selected NIC, verify the displayed IP address. If a selected NIC has multiple IP addresses assigned, double-click the field and choose the desired IP address from the drop-down list. Each IP address can be in a different subnet.
  The IP address is used for the VCS private communication over the specified UDP port.

- For each selected NIC, double-click the respective field in the Link column and choose a link from the drop-down list. Specify a different link (Link1 or Link2) for each NIC. Each link is associated with a UDP port that you specified earlier.
  The wizard configures the LLT service (over UDP) on the selected network adapters. The specified UDP ports will be used for the private network communication.

12 On the VCS Helper Service User Account panel, specify a domain user account for the VCS Helper service. The VCS high availability engine (HAD), which runs in the context of the local system built-in account, uses the VCS Helper service user context to access the network.
  This account does not require Domain Administrator privileges.
Specify a domain user as follows:

- To specify an existing user, do one of the following:
  - Click **Existing user** and select a user name from the drop-down list.
  - If you chose not to retrieve the list of users in step 4 on page 78, type the user name in the **Specify User** field, and then click **Next**.
- To specify a new user, click **New user** and type a valid user name in the Create New User field, and then click **Next**.
  Do not append the domain name to the user name; do not type the user name as Domain\user or user@domain.
- In the Password dialog box, type the password for the specified user and click **OK**, and then click **Next**.

13 On the Configure Security Service Option panel, specify security options for the cluster and then click **Next**.
Do one of the following:

- To use the single sign-on feature, complete the following steps:

  - Click **Use Single Sign-on**. In this mode, the Symantec Product Authentication Service is used to secure communication between cluster nodes and clients, including the Java console, by using digital certificates for authentication and SSL to encrypt communication over the public network. VCS uses SSL encryption and platform-based authentication. The VCS engine (HAD) and Veritas Command Server run in secure mode.
Configuring a cluster using the VCS Cluster Configuration Wizard

For more information about secure communications in a cluster, see the Veritas Storage Foundation and High Availability Solutions Quick Start Guide for Symantec Product Authentication Service.

- If you know the name of the system that will serve as the root broker, click **Specify an existing root broker or a node in this cluster to configure as root broker**, type the system name, and then click **Next**.

  If you specify a cluster node, the wizard configures the node as the root broker and other nodes as authentication brokers. Authentication brokers reside one level below the root broker and serve as intermediate registration and certification authorities. These brokers can authenticate clients, such as users or services, but cannot authenticate other brokers. Authentication brokers have certificates signed by the root.

  If you specify a system outside of the cluster, make sure that the system is configured as a root broker; the wizard then configures all nodes in the cluster as authentication brokers.

- If you want to discover the system that will serve as root broker, click **Discover the root broker systems in the domain** and click **Next**. The wizard will discover root brokers in the entire domain, by default.

- If you want to define a search criteria, click **Scope**. In the Scope of Discovery dialog box, click **Entire Domain** to search across the domain, or click **Specify Scope** and select the Organization Unit from the Available Organizational Units list, to limit the search to the specified organization unit. Use the Filter Criteria options to search systems matching a certain condition.

  For example, to search for systems managed by a user *Administrator*, select ** Managed by** from the first drop-down list, **is (exactly)** from the second drop-down list, type the user name *Administrator* in the adjacent field, click **Add**, and then click **OK**.

  To search for all Windows Server 2003 systems, select **Operating System** from the first drop-down list, **is (exactly)** from the second drop-down list, type *2003* in the adjacent field, click **Add** and then click **OK**.
Table 5-1 contains some more examples of search criteria.

<table>
<thead>
<tr>
<th>1st drop-down list value</th>
<th>2nd drop-down list value</th>
<th>Adjacent field entry</th>
<th>Search result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>is (exactly)</td>
<td>*system</td>
<td>Displays all systems with names that end with <em>system.</em></td>
</tr>
<tr>
<td>Name</td>
<td>is (exactly)</td>
<td><em>vcsnode</em></td>
<td>Displays all systems with names that contain <em>vcsnode.</em></td>
</tr>
<tr>
<td>Operating System</td>
<td>is (exactly)</td>
<td><em>2003</em></td>
<td>Displays all Windows Server 2003 systems.</td>
</tr>
<tr>
<td>Operating System</td>
<td>is (exactly)</td>
<td><em>Enterprise</em></td>
<td>Displays all Windows Server Enterprise Edition systems.</td>
</tr>
<tr>
<td>Operating System Version</td>
<td>is (exactly)</td>
<td>5.*</td>
<td>Displays all systems whose operating system version is 5.x, where x could be 0, 1, 2, etc.</td>
</tr>
</tbody>
</table>

You can add multiple search criterion; the wizard will search for systems that match all the conditions specified.

- **Click Next.** The wizard discovers and displays a list of all the root brokers. Click to select a system that will serve as the root broker and then click **Next.**

If the root broker is a cluster node, the wizard configures the other cluster nodes as authentication brokers. If the root broker is outside the cluster, the wizard configures all the cluster nodes as authentication brokers.
To use VCS user privilege, complete the following steps:

- Click **Use VCS User Privileges** and then type a user name and password. The wizard configures this user as a VCS cluster administrator. In this mode, communication between cluster nodes and clients, including Java console, occurs using the encrypted VCS cluster administrator credentials. The wizard uses the VCSEncrypt utility to encrypt the user password. The default user name for the VCS administrator is **admin** and the default password is **password**. Both are case-sensitive. You can accept the default user name and password for the VCS administrator account or type a new name and password. Symantec recommends that you specify a new user name and password.

After the cluster is configured, you can use this account to log on to VCS using Cluster Management Console (Single Cluster Mode) or Web Console, when VCS is not running in secure mode.

- Click **Next**.

14 Review the summary information on the Summary panel, and click **Configure**.

The wizard configures the VCS private network. If the selected systems have LLT or GAB configuration files, the wizard displays an informational dialog box before overwriting the files. In the dialog box, click **OK** to
Getting started with VCS

Configuring a cluster using the VCS Cluster Configuration Wizard

overwrite the files. Otherwise, click Cancel, exit the wizard, move the existing files to a different location, and rerun the wizard. The wizard starts running commands to configure VCS services. If an operation fails, click View configuration log file to see the log.

15 On the Completing Cluster Configuration panel, click Next to configure the ClusterService service group; this group is required to set up components for the Web Console, notification, and for global clusters. To configure the ClusterService group later, click Finish.

At this stage, the wizard has collected the information required to set up the cluster configuration. After the wizard completes its operations, with or without the ClusterService group components, the cluster is ready to host application service groups. The wizard also starts the VCS engine (HAD) and the Veritas Command Server at this stage.

Note: After configuring the cluster you must not change the names of the nodes that are part of the cluster. If you wish to change a node name, run this wizard to remove the node from the cluster, rename the system, and then run this wizard again to add that system to the cluster.

16 On the Cluster Service Components panel, select the components to be configured in the ClusterService service group and click Next.

- Check the Web Console check box to configure the Cluster Management Console (Single Cluster Mode), also referred to as the Web Console.
Check the **Notifier Option** check box to configure notification of important events to designated recipients.

Check the **GCO Option** check box to configure the wide-area connector (WAC) process for global clusters. The WAC process is required for inter-cluster communication. The GCO Option applies only if you are configuring a Disaster Recovery environment and are not using the Disaster Recovery wizard. The Disaster Recovery chapters discuss how to use the Disaster Recovery wizard to configure the GCO option.

### Configuring the Web Console

This section describes steps to configure the VCS Cluster Management Console (Single Cluster Mode), also referred to as the Web Console.

**To configure the Web console**

1. On the Web Console Network Selection panel, specify the network information for the Web Console resources and click **Next**.

   - If the cluster has a ClusterService service group configured, you can use the IP address configured in the service group or configure a new IP address for the Web console.
   - If you choose to configure a new IP address, type the IP address and associated subnet mask.
Configuring a cluster using the VCS Cluster Configuration Wizard

1. Select a network adapter for each node in the cluster. The wizard lists the public network adapters along with the adapters that were assigned a low priority.

2. Review the summary information and choose whether you want to bring the Web Console resources online when VCS is started, and click Configure.

3. If you chose to configure a Notifier resource, proceed to “Configuring notification” on page 90.
   If you chose to configure global cluster components, proceed to “Configuring the wide-area connector process for global clusters” on page 94.
   Otherwise, click Finish to exit the wizard.

Configuring notification
This section describes steps to configure notification.

To configure notification
1. On the Notifier Options panel, specify the mode of notification to be configured and click Next.

You can configure VCS to generate SNMP (V2) traps on a designated server and send emails to designated recipients in response to certain events.
If you chose to configure SNMP, specify information about the SNMP console and click **Next**.

- Click a field in the SNMP Console column and enter the name or IP address of the console. The specified SNMP console must be MIB 2.0 compliant.
- Click the corresponding field in the Severity column and select a severity level for the console.
- Click **+** to add a field; click **-** to remove a field.
- Enter an SNMP trap port. The default value is 162.
3 If you chose to configure SMTP, specify information about SMTP recipients and click **Next**.

- Type the name of the SMTP server.
- Click a field in the Recipients column and enter a recipient for notification. Enter recipients as admin@example.com.
- Click the corresponding field in the Severity column and select a severity level for the recipient. VCS sends messages of an equal or higher severity to the recipient.
- Click + to add fields; click - to remove a field.
4 On the Notifier Network Card Selection panel, specify the network information and click **Next**.

- If the cluster has a ClusterService service group configured, you can use the NIC resource configured in the service group or configure a new NIC resource for notification.
- If you choose to configure a new NIC resource, select a network adapter for each node in the cluster. Note that the wizard lists the public network adapters along with the adapters that were assigned a low priority.

5 Review the summary information and choose whether you want to bring the notification resources online when VCS is started and click **Configure**.

6 If you chose to configure global cluster components, proceed to “Configuring the wide-area connector process for global clusters” on page 94. Otherwise, click **Finish** to exit the wizard.
Configuring the wide-area connector process for global clusters

This section describes steps to configure the wide-area connector resource required for global clusters.

To configure the wide-area connector process for global clusters

1. On the GCO Network Selection panel, specify the network information and click Next.

   - If the cluster has a ClusterService service group configured, you can use the IP address configured in the service group or configure a new IP address.
   - If you choose to configure a new IP address, enter the IP address and associated subnet mask. Make sure that the specified IP address has a DNS entry.
   - Select a network adapter for each node in the cluster. Note that the wizard lists the public network adapters along with the adapters that were assigned a low priority.

2. Review the summary information and choose whether you want to bring the resources online when VCS starts and click Configure.

3. Click Finish to exit the wizard.
Configuring a cluster from the command line

VCS provides a silent configuration utility, VC\%silent.exe, which enables you to configure only a new cluster and also delete an existing cluster. The silent configuration utility must be used to configure or delete only one cluster at a time.

Preparing for silent configuration

The silent configuration utility requires an XML configuration file, which contains the details of the cluster to be configured. The XML file must be of the following format:

For configuring a non-secure cluster

```xml
<Domain Name="domain_name">
  <SystemList>
    <System Name="sys_name1"/>
    <System Name="sys_name2"/>
    ....
    ....
  </SystemList>
  <Cluster Name="clus_name" ID="clus_ID">
    <Node Name="sys_name1">
      <LLTLink Name="adp_name_1" MAC="MAC_address_1" LowPri="pri"/>
      <LLTLink Name="adp_name_2" MAC="MAC_address_2" LowPri="pri"/>
    </Node>
    <Node Name="sys_name2">
      <LLTLink Name="adp_name_1" MAC="MAC_address_1" LowPri="pri"/>
      <LLTLink Name="adp_name_2" MAC="MAC_address_2" LowPri="pri"/>
    </Node>
  </Cluster>
</Domain>
</Operation>
```
For configuring a secure cluster

<Operation Type="New">
   <Domain Name="domain_name">
      <SystemList>
         <System Name="sys_name_1"/>
         <System Name="sys_name_2"/>
         ....
      </SystemList>
      <Cluster Name="clus_name" ID="clus_ID">
         <Node Name="node_name_1">
            <LLTLink Name="adp_name_1" MAC="MAC_address_1" LowPri="pri"/>
            <LLTLink Name="adp_name_2" MAC="MAC_address_2" LowPri="pri"/>
         </Node>
         <Node Name="node_name_2">
            <LLTLink Name="adp_name_1" MAC="MAC_address_1" LowPri="pri"/>
            <LLTLink Name="adp_name_2" MAC="MAC_address_2" LowPri="pri"/>
         </Node>
         ....
      </Cluster>
      <Security Type="Secured">
         <VxSSRoot Name="root_name"/>
      </Security>
      <HadHelperUser Name="HAD_user_name" Password="password"/>
   </Domain>
</Operation>
For deleting a non-secure cluster

```
<Operation Type="Delete">
  <Domain Name="domain_name">
    <SystemList>
      <System Name="sys_name1"/>
      <System Name="sys_name2"/>
      ....
    </SystemList>
    <Cluster Name="clus_name" ID="clus_ID"
      ConnecttoCluster="ConnecttoClustervalue"
      IgnoreOfflineGroups="IgnoreOfflineGroupsvalue">
      <Security Type="Non-Secured">
        <Admin User="admin_user_name" Password="password"/>
      </Security>
      <HadHelperUser Remove="Removevalue" Name="HAD_user_name" Password="password"/>
    </Cluster>
  </Domain>
</Operation>
```

For deleting a secure cluster

```
<Operation Type="Delete">
  <Domain Name="domain_name">
    <SystemList>
      <System Name="sys_name_1"/>
      <System Name="sys_name_2"/>
      ....
    </SystemList>
    <Cluster Name="clus_name" ID="clus_ID"
      ConnecttoCluster="ConnecttoClustervalue"
      IgnoreOfflineGroups="IgnoreOfflineGroupsvalue">
      <Security Type="Secured">
        <VxSSRoot Name="root_name"/>
      </Security>
      <HadHelperUser Remove="Removevalue" Name="HAD_user_name" Password="password"/>
    </Cluster>
  </Domain>
</Operation>
```

Copy the relevant format to any text editor and save it with a .xml extension. Replace the variables, shown in italics, with appropriate values. Review the information about variables and their possible values.

See "Values for element attributes" on page 98.

A sample XML file is included for your reference.

See "Sample XML configuration" on page 100.
Values for element attributes

The following table describes the variables used in the XML format and their possible values:

<table>
<thead>
<tr>
<th>Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>domain_name</strong></td>
<td>Replace this with the fully qualified name of a domain in which the systems reside.</td>
</tr>
<tr>
<td><em><em>sys_name_&lt;n</em>&gt;</em>*</td>
<td>Replace this with name of the system in the domain for which relevant information will be discovered. Note: For each system, you must have a System child element under the SystemList element.</td>
</tr>
<tr>
<td><strong>clus_name</strong></td>
<td>Replace this with the name of the cluster to be created.</td>
</tr>
<tr>
<td><strong>clus_ID</strong></td>
<td>Replace this with the cluster ID. Make sure you specify a unique cluster ID between 0 and 255.</td>
</tr>
<tr>
<td><em><em>node_name_&lt;n</em>&gt;</em>*</td>
<td>Replace this with the name of the system that will be part of the cluster. Make sure you provide system names from the list of systems that are specified under the SystemList element. For example, if you specified SysA and SysB in the SystemList element, you may specify one or both the systems for the node names. However, you should not specify another system, say SysC, which was not specified in the SystemList element. Note: For each node, you must have a Node child element along with the LLTLink subchild element under the Cluster element.</td>
</tr>
<tr>
<td><em><em>adp_name_&lt;n</em>&gt;</em>*</td>
<td>Replace this with the name of the adapter on which the LLT link will be configured. Note: For each node, you must specify a minimum of two adapters. Each adapter must be specified as an attribute of the LLTLink element.</td>
</tr>
<tr>
<td><em><em>MAC_address_&lt;n</em>&gt;</em>*</td>
<td>Replace this with the MAC address of the adapter.</td>
</tr>
<tr>
<td><strong>Pri</strong></td>
<td>Replace this with either &quot;1&quot; or &quot;0&quot;. Value &quot;1&quot; indicates the adapter is assigned a low priority. Value &quot;0&quot; indicates otherwise. You may assign a low priority to an adapter to use it for both private and public network communication.</td>
</tr>
</tbody>
</table>
Getting started with VCS

Configuring a cluster from the command line

Table 5-2  VCWSilent - variables and values (continued)

<table>
<thead>
<tr>
<th>Variables</th>
<th>Description</th>
</tr>
</thead>
</table>
| admin_user_name   | Replace this with a user name for the cluster administrator. You may use this user name to log on to a cluster using Cluster Manager.  
Note: This is applicable only for a non-secure cluster. |
| root_name         | Replace this with a system name that will be configured as the root broker for all the systems in the cluster. If you provide a system that is not specified under the Node element, make sure the system is configured as a root broker.  
Note: This is applicable only for a secure cluster. |
| HAD_user_name     | Replace this with a domain user name in whose context the VCS Helper service will run. The VCS High Availability Daemon, which runs in the context of the local system built-in account, uses the VCS Helper service user context to access the network. |
| password          | Replace this with an encrypted password.  
See “Encrypting passwords” on page 100 for instructions. |
| ConnectToCluster  | Replace this with “Yes” if you wish to connect to the cluster before deleting it. If the connection fails, the cluster deletion does not proceed.  
The default value is “No”. This means that the cluster is deleted without connecting to it. |
| IgnoreOfflineGroups| Replace this with “Yes” if you wish to delete the cluster along with the service groups that are configured in the cluster.  
The default value is “No”. This means that the cluster deletion does not proceed if there are service groups in the cluster. |
| Remove            | Replace this with “Yes” if you wish to delete the VCS Helper Service account along with the cluster.  
The default value is “No”. This means that the VCS Helper account will not be deleted. |

* “n” is the sequence number for the systems, nodes, adapters, and MAC addresses.
Encrypting passwords

Before specifying passwords in the XML configuration file, you must encrypt them using the vcsencrypt utility.

Note: If User Access Control (UAC) is enabled on Windows Server 2008 systems, you must launch the command prompt in the Run as administrator mode and then run the commands mentioned in this procedure. To launch the command prompt in the administrator mode, right-click the command prompt shortcut from the Windows Start menu and click Run as administrator from the context menu.

To encrypt a password

Perform these steps for all the passwords to be specified in the XML file.

1. Run the vcsencrypt utility. Type the following on the command line.
   
   C:\> vcsencrypt -agent

2. The utility prompts you to enter the password twice. Enter the password and press Return.
   
   Enter New Password:
   Enter Again:

3. The utility encrypts the password and displays the encrypted password.

4. Specify this encrypted password in the XML file.
   Copy the encrypted password for future reference.

Sample XML configuration

Sample XML configuration files are provided for reference.

Two-node secure cluster configuration

This configuration file can be used to create a secure cluster with systems SYSTEM1 and SYSTEM2.

```
<Operation Type="New">
  <Domain Name="DOMAIN.com">
    <SystemList>
      <System Name="SYSTEM1"/>
      <System Name="SYSTEM2"/>
    </SystemList>
    <Cluster Name="MYCLUSTER" ID="0">
      <Node Name="SYSTEM1">
        <LLTLink Name="Adapter0" MAC="00:03:47:08:91:56" LowPri="0"/>
      </Node>
      <Node Name="SYSTEM2">
        <LLTLink Name="Adapter1" MAC="00:03:47:08:91:C6" LowPri="0"/>
      </Node>
    </Cluster>
  </DomainList>
</Operation>
```
Two-node secure cluster deletion
This configuration file can be used to delete a secure cluster with systems SYSTEM1 and SYSTEM2.

<Operation Type="Delete">
  <Domain Name="DOMAIN.com">
    <SystemList>
      <System Name="SYSTEM1"/>
      <System Name="SYSTEM2"/>
    </SystemList>
    <Cluster Name="MYCLUSTER" ID="0" ConnecttoCluster="No" IgnoreOfflineGroups="Yes">
      <Security Type="Secured">
        <VxSSRoot Name="SYSTEM1"/>
      </Security>
      <HadHelperUser Remove="No" Name="Administrator" Password="hvnTkvK"/>
    </Cluster>
  </Domain>
</Operation>
Performing a silent configuration

Review the prerequisites before running the silent configuration utility, VCWsilent.exe.

See “Prerequisites” on page 76.

**Note:** If User Access Control (UAC) is enabled on Windows Server 2008 systems, you must launch the command prompt in the Run as administrator mode and then run the VCWSilent utility from the command prompt. To launch the command prompt in the administrator mode, right-click the command prompt shortcut from the Windows Start menu and click Run as administrator from the context menu.

You may run the utility from any system in the domain, irrespective of whether the system will be part of the cluster being configured.

To run the silent configuration utility

1. From the command line, navigate to the directory containing the XML configuration file and run the VCWsilent utility. Type the following on the command line:
   ```
   C:\<XML_file_location> VCWsilent <name of XML file>
   ```
   To view the progress of the silent configuration, use the "-v" option. Type the following on the command line:
   ```
   C:\<XML_file_location> VCWsilent <name of XML file> -v
   ```

2. If the cluster is successfully configured or deleted, the following message is displayed:
   Silent configuration was successful.
   If the silent configuration fails, an error message is displayed. Review the message associated with the failure and rerun the utility after rectifying the problem.

Analyzing a domain

The VCS Cluster Configuration Wizard (VCW) analyzes a domain and creates a report about clusters and systems in the domain. The wizard retrieves information about whether VCS is installed and configured on systems, and about the network configuration of cluster nodes.

To analyze a domain and create an analysis report

1. Start the VCS Configuration Wizard. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Cluster Configuration Wizard)
2 Read the information on the Welcome panel and click **Next**.

3 On the Configuration Options panel, click **Analyze Domain** and click **Next**.

4 On the Domain Selection panel, select or type the name of the domain to be analyzed and click **Next**. Review the information in the message box and click **Yes**.

5 On the Domain Analysis for VCS panel, select the clusters and systems to view their respective details.

   - Select an operating system.
   - Double-click **Clusters** to view the clusters running the selected operating system.
   - Select a cluster name to view the cluster ID and the number of nodes in the cluster.
   - Double-click a cluster name to view the nodes in the cluster.
   - Select a node to view its node ID and the number of LLT links configured on the node.
   - Double-click **Available Systems** to view the systems that have VCS installed but not configured. You can use the wizard to add these nodes to a new cluster, or to form a new cluster with these nodes.
   - Select a system to view the install path for VCS and the number of adapters on the system.
   - Click **Next**.
Specify the options for generating a domain analysis report.

- In the Cluster Details box, select the operating system that the cluster nodes are running.
- Check the **Node Details** check box to obtain information about the nodes in the cluster.
- Check the **LLT Link Details** check box to obtain information about the LLT links between the cluster nodes.
- In the Available System Details box, select the operating system that the systems are running.
- Check the **Network Card Details** check box to obtain information about the network adapters on the systems.
- Click **Save**.

Click **Finish** to exit the wizard.

The wizard generates the report in the XML format and saves it under the user profile in whose context the wizard was run, typically `%APPDATA%\veritas\cluster server\VCWAnalysis.xml`. For Windows 2003, `%APPDATA%` is typically `C:\Documents and Settings\<user profile>\Application Data\`. For Windows 2008, `%APPDATA%` is typically `C:\Users\<user profile>\AppData\Roaming`.

## About Veritas Cluster Management Console

Veritas Cluster Management Console offers web-based cluster administration and management. It can be configured to locally manage a single cluster or to centrally manage multiple clusters.

For information on installing the console to manage multiple clusters, see the *Veritas Cluster Server Management Console Implementation Guide*.

<table>
<thead>
<tr>
<th>Operational mode</th>
<th>Configurational description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local management of one cluster (single-cluster mode)</td>
<td>The Cluster Management Console is installed along with VCS on each node in the cluster and is configured for failover. The console is integrated with VCS as part of the ClusterService service group. The Cluster Management Console offers robust cluster management capability and can be run from any supported Web browser on any system.</td>
</tr>
<tr>
<td>Centralized, comprehensive, enterprise-wide administration of multiple clusters (multi-cluster mode)</td>
<td>When configured to centrally administer multiple clusters, one instance of the Cluster Management Console is installed outside all clusters on a standalone management server. The management server uses a database to store cluster configurations, cluster status, events, event policies, report jobs, report outputs, and more. If the management server and cluster nodes are separated by a firewall, a component called <em>cluster connector</em> is installed on each cluster node. The console offers additional capability for administering users, reports, events, and notification. If the cluster environment includes licensed VCS global clusters, disaster recovery (DR) capability is also available.</td>
</tr>
</tbody>
</table>
Supported browsers

Veritas Cluster Management Console is supported on the following browsers:

- Microsoft Internet Explorer 6.0 or later
- Firefox 1.5 or later

Veritas Cluster Management requires the Macromedia Flash Plugin v8.0.

Configuring the Cluster Management Console manually

The resources required for the Cluster Management Console are configured in the ClusterService group. This configuration is performed by the VCS installation program if the Cluster Management Console option is selected during installation. If the Cluster Management Console option was not selected during VCS installation, you must create and configure the ClusterService service group manually.

Review the instructions on configuring the console using the VCS Cluster Configuration Wizard.

See “Configuring the ClusterService group” on page 445.

To configure the Cluster Management Console

1. Create a service group called ClusterService.

2. Add a resource of type NIC to the service group. Name the resource csgnic. Configure the following attributes for the resource:
   - MACAddress: The physical address of the adapter to be configured to host the virtual IP.
   - UseConnectionStatus: A flag that defines whether the NIC maintains its connection status.

3. Add a resource of type IP to the service group. Name the resource webip.

4. Configure the following attributes for the IP resource:
   - Address: A virtual IP address to be assigned to the console. The console will be accessed using this IP address.
   - MACAddress: The physical address of the adapter on the system from which the console will run. MACAddress is defined as a local attribute for each system in the cluster.
   - SubnetMask: The subnet to which the virtual IP address belongs.
   - Critical: Set this attribute to True to make webip a critical resource.
5 Add a resource of type VRTSWebApp to the service group. Name the resource VCSweb. Configure the following attributes for the resource:

- **Appname**: Set to cmc.
- **InstallDir**: Set to the path at which VRTSweb was installed, typically C:\Program Files\VERITAS\VRTSWeb\VERITAS.
- **TimeForOnline**: Set to 5.
- **Critical**: Set this attribute to True to make VCSweb a critical resource.

6 Create the following resource dependencies:

- Link the csgnic and webip resources such that the webip resource depends on the csgnic resource.
- Link the VCSweb and webip resources, such that the VCSweb resource depends on the webip resource.

7 Enable all resources in the service group.

8 Bring the ClusterService service group online. You can now access the console at the URL http://IP_alias:8181/cmc. The variable IP_alias is the virtual IP address configured in the service group.

Sample configuration

```plaintext
group ClusterService {
  SystemList = { SYSTEM7, SYSTEM8 }
  UserStrGlobal = "10.182.145.34_14141@https://169.254.106.13:8443;"
  AutoStartList = { SYSTEM7, SYSTEM8 }
}

IP webip {
  Address = "10.182.147.14"
  SubNetMask = "255.255.252.0"
  MACAddress @SYSTEM7 = "01-44-13-D4-2D-E0"
  MACAddress @SYSTEM8 = "00-50-04-A4-1A-D0"
}

NIC csgnic {
  MACAddress @SYSTEM7 = "01-44-13-D4-2D-E0"
  MACAddress @SYSTEM8 = "00-50-04-A4-1A-D0"
}

VRTSWebApp VCSweb {
  Critical = 0
  AppName = cmc
  InstallDir = "\"C:\\Program Files\\VERITAS\\VRTSWeb\\VERITAS\""
  TimeForOnline = 5
}

webip requires csgnic
VCSweb requires webip
```
Logging in to the Cluster Management Console

The Cluster Management Console is a web application that is installed on a VCS node. You must log in to the Cluster Management Console to manage your VCS cluster. To run the console, the local system (the system you use to run the console) must also be running a supported web browser.

To log in to the console

1. In your Internet browser, enter the URL address configured for the Cluster Management Console during installation. You can enter either:
   - `https://System:8443/cmc/`

   where `System` is either a system name or the virtual IP address configured for the webip resource in the ClusterService service group.

   On Windows, you can click `Start > Programs > Symantec > Veritas Cluster Server > Cluster Management Console - Web Console`
   to view the log in screen.

   Before connecting to the console, make sure the console is configured and the ClusterService group is online.

2. Under **Please enter a web-admin username and password to continue**, select a language from the drop-down menu.

3. Enter a valid user name and password for the cluster.
   - On UNIX, the default user account is the local root account.
   - On Windows, the default user account is the account that was used to perform the VCS installation.

4. Enter the domain name associated with the account and then click **Login**. If the user account you are using to connect is not a domain account, enter the fully-qualified system name for the local host system. The local host is the cluster node running the Cluster Management Console.

Logging out of the Cluster Management Console

Log out to end a Cluster Management Console session.

To log out of the console

- On the title bar of the Cluster Management Console, click **Logout**.
Overview of the Cluster Management Console

The Cluster Management Console consists of several views. Before you start your first Cluster Management Console session, use this material to familiarize yourself with the default view, navigation methods, and icon representations used in the console.

Note: The console enables or restricts certain views depending on your privileges. For example, you are a user with a privilege level of guest or operator, certain tabs or task links in the console may be unavailable.

Cluster Management Console layout

Logging in to the management server starts the Cluster Management Console. The startup view is the Cluster:Summary view.

Figure 6-1 Cluster Management Console default view

All views in the Cluster Management Console are divided into areas called bars, panes, panels, and tables.
About the main tab bar

The main tab bar contains a tab, representing a set of views, for each category of operations available in the Cluster Management Console. The tabs are: Manage (management) for cluster object configuration and manipulation, and Search for conducting and saving character-based searches on management server and cluster objects.

Clicking a tab takes you to the initial view for that tab. The main tab bar always contains the same tabs.

About the search bar

The search bar contains a text edit box next to a Search button.

The search bar enables you to find any management server object or cluster object in the management server database.

About the task pane

The left pane of the console is the task pane. The task pane contains one or more task panels, depending upon the view selected. In the startup view, the task pane contains the Alerts and Configuration task panels. The task pane can contain as many as four task panels.

The task pane contains a narrow button on the border that separates it from the status pane on the right. This button toggles the task pane between maximum and minimum size. In the startup view, click this button to minimize the task pane. Minimizing the task pane hides the Configuration task panel and enlarges the status pane, enabling you to view information that might have been partially off-screen.

Click the narrow button again to maximize the task pane. Even with the task pane maximized, you can still display off-screen information in the status pane using the scroll bar located along the bottom border of any view.

About task panels

The task panels in the task pane list specific operations that you can perform in each view of the Cluster Management Console. For views that list specific objects (clusters, service groups, systems, and so on), the task panels list all the possible tasks that you can perform on those objects. Tasks related to object management are usually divided between two task panels named Operations and Configuration.

The name of a task panel indicates the type of tasks listed in that panel. Underlined tasks indicate a link that performs an action directly or which starts a task wizard (sequence of dialog boxes that help you to perform a task).
For views that show details for a specific object, some tasks may not be linked (underlined). Unlinked tasks can indicate one or both of the following:

- The tasks cannot be performed on the object or objects that you are viewing
- Your current user role does not authorize you to perform those tasks.

**About filter panels**

Many views contain a filter panel in the task pane. A filter panel enables you to view only those objects that meet the criteria you specify. You specify the filter criteria using controls such as check boxes or drop-down menus. If you want to perform a task on only certain objects, you can first filter the view for those objects and then select the task. The following are the possible filter names and settings:

- By Consolidated State – shows objects with the following values for the ConsolidatedState attribute:
  - Online - shows responsive, functioning objects
  - Offline - shows unresponsive, nonfunctioning objects
  - Partial - shows objects (clusters or service groups) in which one or more, but not all, member objects have experienced a fault
  - Faulted - shows objects that have experienced a fault
  - Unknown - shows objects in an undetermined consolidated state

- Global Groups – shows service groups configured using VCS GCO features.

**About the Alerts panel**

The Alerts panel is a special panel in the task pane that provides current counts of active alerts, categorized by severity. The Alerts panel is in the task pane of every view in the Cluster Management Console.

**Figure 6-2** Alert severity icons

- Critical
- Error
- Warning
- Information
Collapsing and expanding panels in the task pane
Clicking the up arrow in the center top of each task or filter panel collapses the panel to show only the heading.
When a panel is collapsed, the up arrow changes to a down arrow. When you click the down arrow, the panel expands to show the panel contents.

About the status pane
The status pane can contain many different panels and tables depending upon the view selected. These panels and tables contain status information about the cluster objects detailed by the selected view. In the startup view, the status pane contains panels labelled Faulted Groups, Groups, and Systems, and a table labelled Critical and Error logs in last eight hours.

Figure 6-3 Status pane in the startup (Cluster:Summary) view

The Manage tab, secondary tabs, and the view hierarchy
The Management tab on the main tab bar represents the main category of tasks and information in the console. It also marks the beginning of a multi-level navigation path, or view hierarchy. The management tab “branches down” into a set of levels, and each level contains a set of views.
Under the Manage tab, the first level “down” is called cluster. The cluster level under the Management tab indicates that you are viewing your cluster environment at the highest and broadest level possible. From the cluster level, you can navigate to views that contain information about any object configured in the cluster.
Each level in the view hierarchy contains a set of views. You can navigate to these views using the secondary tab bar. The secondary tab bar is located along the top of the status pane and contains a row of one or more tabs. Each tab represents a view at a level in the view hierarchy.

On the Manage tab, the view hierarchy levels are cluster, service group, system, resource, and resource type. Each level contains views represented by the tabs on the secondary tab bar.

**Table 6-1  Levels and views in the Manage tab view hierarchy**

<table>
<thead>
<tr>
<th>Level in the Manage tab view hierarchy</th>
<th>Views available at this level (tabs on the secondary tab bar)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster</td>
<td>Summary, Groups, Systems, Attributes, Resources, Service Group Dependency, Resource Types, DR Alerts, Cluster Heartbeats, Users, Logs</td>
</tr>
<tr>
<td>Service group</td>
<td>Summary, Attributes, Resources, Logs</td>
</tr>
<tr>
<td>System</td>
<td>Summary, Attributes, Logs</td>
</tr>
<tr>
<td>Resource</td>
<td>Summary, Resource Dependency, Attributes, Logs</td>
</tr>
<tr>
<td>Resource type</td>
<td>Attributes</td>
</tr>
</tbody>
</table>

On the secondary tab bar, one tab is always active (selected); that tab represents your position at current level in the view hierarchy. For example, if you are at the startup view, Cluster:Summary, the Summary tab is active. According to the table, you are in the first position at the cluster (first, highest) level. If you are at the Cluster:Groups view, the Groups tab is active. According to the table, you are at the second position at the cluster (third) level.

As you “drill down” into lower and lower view levels (using tabs and other links), the number and variety of the objects and tasks available to you generally becomes fewer and fewer.

**About the navigation bar**
The navigation bar is located along the top of the status pane and indicates two things:

- Your current level in the current view hierarchy.
- The “lineage” of the object detailed in your current view.

For example, assume that you are at the startup view, the Cluster:Summary view. The navigation bar shows [Cluster], where Cluster is the name of the local managed cluster (the cluster on which VCS is installed). [Cluster] alone, with no additional links in the trail, indicates that you are at the top level of views.
Now assume that you perform the following actions in order (if you are currently using the console, follow along):

- Click a cluster name in the table
- Click the Groups tab
- Click a service group name in the table
- Click the Resources tab
- Click a resource name in the table

You arrive at a Resource:Summary view. The navigation bar shows a list of the objects that you selected to navigate to this view. The object names are shown in the following format:

Cluster >> Service Group >> Resource

These objects are also the parent objects of the resource you selected. The navigation trail ends with the selected resource name. This tells you that you are at the resource level of views.

Figure 6-4 Navigation bar with a resource selected.

The path on the navigation bar is also called a navigation trail. Object names higher up (listed nearer the beginning) of the trail are underlined, indicating that they are a navigation link to the level of views for those objects. You can move quickly up and down a view hierarchy by clicking linked object names.

About the view name
The view name appears immediately below the navigation trail. The view name is a unique name for the current view that also indicates:

- Your current level in the view hierarchy, as indicated by the navigation trail
  
  Your “current level” is the level that the current view occupies in the view hierarchy, such as cluster, group, or resource.

- Your current position within the current level, as indicated by the secondary tab bar
  
  Your “current position” is the position that the current view occupies within the current level. The position is the name of whichever tab is selected on the secondary tab bar, such as Summary, Attributes, or Logs.

For example:

- According to the view hierarchy table, the view name Cluster:Resources indicates that this view is the fifth view at the cluster level. It contains
cluster-level information about resources and enables you to view the status of resources that are members of the cluster.
See the table “Levels and views in the Manage tab view hierarchy” on page 114.

- The view name Group:Summary indicates that this view is the first view at the service group level. It contains summary information about a service group and enables you to view a composite status of the service group.

About quick navigation links
In many views, the status panel contains underlined object names. For example, the name of the cluster in the Cluster:Summary view links to a detail view for the objects that are members of that cluster. Likewise, clicking other underlined objects in the status panel takes you to a detail view for those objects.

Figure 6-5 Quick navigation links in the status panel (links are underlined)
**Icon conventions**

The Cluster Management Console uses the following icons to represent cluster objects:

<table>
<thead>
<tr>
<th>Table 6-2</th>
<th>Object icons</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Cluster" /></td>
<td>Cluster</td>
</tr>
<tr>
<td><img src="image" alt="Group" /></td>
<td>Group</td>
</tr>
<tr>
<td><img src="image" alt="System" /></td>
<td>System</td>
</tr>
<tr>
<td><img src="image" alt="Resource" /></td>
<td>Resource</td>
</tr>
<tr>
<td><img src="image" alt="Resource type" /></td>
<td>Resource type</td>
</tr>
</tbody>
</table>

General status indicators are applied to the basic object icons to create status icons. Status icons indicate both the type and the state of the object. The following are the status indicators:

- Color icons indicate objects that are in a healthy, running condition.
- Gray icons indicate objects that are offline.
- Icons with orange lines indicate objects that are partially online with only some member (contained) objects online.
- Icons with red lines indicate faulted objects.
- Icons with a question mark indicate objects whose status is unknown.
- Icons with a red lock indicate objects in a frozen state.
- Icons with a red circle and white cross bar indicate objects in an autodisabled state.
Sorting the contents of a data table

In some Cluster Management Console tables, you can sort the rows by the data in a column. Some columns are not sortable.

To sort rows in a table by data in a column

1. In the table, locate a column you want to use to sort the data.
2. Click the column heading.
   - The list is sorted by the values in that column, in ascending order. A triangle (pointing up) displays in that column heading.
3. If desired, click the column heading a second time.
   - The list is sorted by the values in that column, in descending order. A triangle (pointing down) displays in that column heading.

Viewing multiple pages of a data table

Tables in Cluster Management Console views may contain multiple pages. You can view subsequent pages of a table using the go-to-page bar.

To access pages in a table

◆ In a table with multiple pages, locate the go-to-page bar just below the table.

Figure 6-6 Go-to-page bar

Click the controls on the go-to-page bar to move forward and backward through the table pages. The following are the controls on the go-to-page bar and their meaning:

- Numerals (1,2,3...) Go to that page number
- Single right arrow Go to next page
- Single left arrow Go to previous page
- Double right arrow Go to last page
- Double left arrow Go to first page
Controlling view updates

As you use the console, the status of the cluster, systems, and applications will probably change. Devices go online and offline, alerts are generated, and application data fluctuates. You can control when and how the information in your console display updates (refreshes) to reflect the latest data.

Update (refresh) mode settings and icons

An update icon near the top right-hand corner of the Cluster Management Console indicates the current update mode and the state of the information displayed in the console. Clicking the update icon enables you to set the update mode. The appearance of the update icon changes according to the following update modes:

■ **Disabled**
  Provides no indication of available updates (disables update notification). Use the refresh function in your web browser to update the console information.

■ **Notify Only**
  Indicates when data updates are available. Icon changes to the Refresh Notification icon when data updates are available.
  For the **Notify Only** setting, when data is no longer current, the Page is Stale icon appears. This is the default setting. Click this icon to update the console information.

■ **Auto Refresh**
  Automatically updates the console information when it is no longer current.

**To change the refresh mode**

◆ Click the update icon to cycle among the refresh modes. You can select any mode except **Page is Stale**.

**To use the Search feature**

1. In the help viewer window, click the **Search** tab.
2. Enter the term to be searched in the field provided. The Cluster Management Console help system displays all matches for this term.
3. Select an item to display the help topic for that item.
Administering users

Users can be created with the roles of cluster administrator, cluster operator, or cluster guest. They can also be created with the roles of service group administrator, service group operator, or service group guest, for specific service groups.

See "About the VCS user privilege model" on page 67.

You can view a list of users in the Cluster:Users view.

To navigate to the list in the Cluster:Users view

1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Users.

In the Cluster:Users view, you can choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

About user listing tables

The following is a list of the columns and data in tables that list user information.

- Name - the user name string
- Privileges - the roles assigned to the user
- Assign Privileges - a button that takes you to the role assignment part of the Add User wizard.
  See “Adding and deleting a user” on page 121.
- Delete - a button that prompts you to delete the user

Sorting the list

You can sort a user listing table according to your needs:

To sort users

1. In the user listing table, locate the column by which you want to sort the list.
2. Click the column heading.

The list is sorted by the values in the selected column in ascending order. A triangle (pointing up) displays in that column heading. Click the column heading again to reverse the sort; this action also reverses the triangle.
Adding and deleting a user

Users must have a role assigned on the cluster before they can perform any management tasks.

To add a cluster user

1. In the Cluster:Users view, in the Configuration task panel, click Add a user.
2. In the New User wizard, specify the following new user details and then click Next:
   - The new user name.
   - If the target cluster is not configured in secure mode, you must also specify a password for the new user and confirm it.
3. In the Assign Privileges dialog box, specify the following options and then click OK:
   - The role
     The available roles for a cluster user are Cluster Administrator, Cluster Operator, Group Administrator, or Group Operator. You can select more than one, but be aware that some option combinations are redundant.
   - The objects to which the role grants authority
     To begin this procedure, you selected a single cluster from a Clusters Listing table. If you select a role of Cluster Administrator or Cluster Operator, you have already specified the object to which the user’s role applies. You are not required to specify anything more, so the service group selection boxes are unavailable.
     If you select Group Administrator or Group Operator, you must select at least one service group. To select a service group, click a service group name under Available Groups and then click the right-arrow button. To reject a service group, click a name under Selected Groups and then click the left-arrow button to return it to Available Groups.

Note: This procedure does not validate the user account. For a cluster that is configured in secure mode, the account is assumed to exist on the domain. For a cluster that is not configured in secure mode, the account is assumed to exist on the cluster.
To delete a cluster user

1. In the Cluster:Users view, in the Delete column of the Users table, click the X button at the end of the line item corresponding to the user that you want to delete.

2. In the Delete User dialog box, click OK to confirm that you want to delete the selected user.

---

**Note:** You cannot delete the user account that is currently logged in.
Administering a cluster

The Cluster Management Console enables you to initially set and then modify the parameters of the VCS cluster configuration. After opening the configuration, you can save it to disk. Use the Cluster:Summary view to administer the cluster.

To navigate to the Cluster:Summary view
1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary.
   In the Cluster:Summary view, you can choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

Opening the configuration
You can modify a read-only configuration file to a read-write file by opening the configuration. This task is available only when the cluster configuration has been saved in read-only mode.

To open a configuration
1. In the Cluster:Summary view, in the Configuration task panel, click Open Configuration.
2. In the Open Configuration dialog box, click OK to confirm that you want to open the configuration in read-write mode.

Saving the configuration
After updating the VCS cluster configuration, save it to disk in either read-only or read-write mode.

To save the configuration
1. In the Cluster:Summary view, in the Configuration task panel, click Save Configuration.
2. In the Save Configuration dialog box, check the Make Configuration Read-Only option to save the configuration in read-only mode, or leave it clear to save the configuration in read-write mode.
3. Click OK.
Modifying cluster attributes

Edit the attributes of a cluster. You must have the role of cluster administrator to edit cluster attributes.

To edit a cluster attribute using the attribute table

1. In the Cluster:Summary view, on the secondary tab bar, click Attributes.
2. In the All attributes for cluster table, locate the line item for the attribute you want to edit.
3. In the Edit column, click the... (edit) button.
4. In the Edit Attribute dialog box, specify the following attribute details and then click OK:
   - The attribute value
     In the Values field, either click a value to change it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value.
     You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.
   - The systems on which to change the attribute
     Specify a setting for the Apply value to option. Apply to all nodes applies the changes to all systems listed the System List, which lists all systems on which the attribute is configured. Apply to selected nodes enables you to select nodes from the System List.
Administering service groups

The Cluster Management Console enables you to add and configure a service group according to the requirements of the application that the service group supports. Use the following views to administer a service group:

- **Cluster:Groups**
  This is a cluster-level view of all service groups in the cluster.

- **Group:Summary**
  This is the first view at the service group level in the Cluster Management Console.

**To navigate to the Cluster:Groups view**
1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary, and then click Groups.
   In the Cluster:Groups view, the Service Groups Listing table lists all service groups in the selected cluster. The task panels contain several tasks that you can perform in a one-to-many fashion on the listed service groups.

**To navigate to the Group:Summary view**
1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary and then click Groups.
3. In the Cluster:Groups view, in the Groups Listing table, click a linked service group name.
   In the Group:Summary view, you can choose a task from the task pane or select another service-group-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering a single service group.

Adding a service group to a cluster

Add and configure a service group as a member of the cluster. You must have the role of cluster administrator to add a service group to a cluster.

**To add a service group to a cluster**
1. In the Cluster:Groups view, in the Configuration task panel, select Add Service Group.
2. In the Service Group Configuration wizard, read the introductory text and then click Next.
3 In the **Service Group Configuration** dialog box, specify the following details of the new service group and then click **Next**:

- The service group name
  Enter the name into the **Service Group Name** text box. Service group names must:
  - Consist of only one string
  - Not contain special characters like . (period) or & (ampersand).
  - Begin with an alphabetic character.
  The remaining characters in the name can be letters, digits, hyphens, or underscores.

- The service group type
  Click either **Failover** or **Parallel** to specify the service group type. See “**Types of service groups**” on page 26.

4 In the **System List Configuration** dialog box, specify the following details for the **target** system and then click **Next**. (The target system is the system on which you configure the service group.)

- The target system name
  Find the system you want in the list under **Select and Add Systems**. To quickly find a specific system, click **Filter**, type a few letters of the system name, and then click **Apply**.
  To select a system, click the system name under **Select and Add Systems** and then click the right-arrow button to move it under **Selected Systems**. You can select multiple systems. To reject a system, click the system name under **Selected Systems** and then click the left-arrow button. This action moves the system back under **Select and Add Systems**.

- The startup system
  Under **Select and Add Systems**, check the **Startup** option next to a system name if you want the service group to startup automatically on that system.

5 In the **Resource Configuration** dialog box, specify the following details about the resources and the service group and then click **Next**:

- The resource name
  Enter the name of the resource that you want to add to the service group into the **Resource Name** text box. Resource names must:
Administering the cluster from the Cluster Management Console

Administering service groups

- Consist of only one string
- Not contain special characters like . (period) or & (ampersand).
- Begin with an alphabetic character.
  The remaining characters in the name can be letters, digits, hyphens, or underscores.

- The resource type
  Select the type of the new resource from the Resource Type drop-down menu.

- The resource startup state
  If you want the resource to start in an enabled state after the service group comes online, check Enable Resource.

- The resource list for the service group
  Click Add Resource to add the resource to the member resource list for the service group. The resource list is used to populate the Resource List table.
  In the Resource List table, you can edit resource attributes or delete a resource using the buttons in the Edit and Delete columns.

6 If you need to link one or more resources, provide the following relationship details in the Link/Unlink Resource dialog box and then click Finish. Otherwise, click Finish now to exit the wizard and create the new service group.

- The parent resource
  Use the Parent Resource drop-down menu to specify which resource must be brought online after the child resource.

- The child resource
  Use Child Resource list box to select which resource should be brought online first, and then click Add Link.

Deleting a service group from a cluster

Manually remove a service group from cluster membership. You must have the role of cluster administrator to remove a service group from a cluster.

You cannot delete a service group if it is a child in a dependency. You must first remove the dependency and then delete the service group.

See “Unlinking service groups” on page 136.

To delete a service group from a cluster

1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the service group that you want to delete.
2. In the **Group:Summary** view, in the **Configuration** task panel, click **Delete Service Group**.

3. In the **Delete Service Group** dialog box, click **OK** to confirm that you want to delete the specified service group.

**Modifying a service group**

Edit a service group configuration. You cannot edit the service group name or type using this task. To change the name or type, you must first remove the service group and then add it back using the desired name and type. You must have the role of cluster administrator or service group administrator to edit a service group.

**To edit a service group configuration**

1. In the **Cluster:Groups** view, in the **Groups Listing** table, click the linked name of the service group that you want to modify.

2. In the **Group:Summary** view, in the **Configuration** task panel, click **Modify Service Group**.

3. In the **Service Group Configuration** wizard, read the introductory text and then click **Next**.

4. In the **Service Group Configuration** dialog box, the service group name and type display but cannot be modified using this task. Click **Next**.

5. In the **System List Configuration** dialog box, specify the following details for the **target** systems and then click **Next**. (The target systems are the systems on that can host the service group.)

   - **The target system names**
     - Find the system you want in the list under **Select and Add Systems**. To quickly find a specific system, click **Filter**, type a few letters of the system name, and then click **Apply**.
     - To select a system, click the system name under **Select and Add Systems** and then click the right-arrow button to move it under **Selected Systems**. You can select one or more systems.
     - To reject a system, click the system name under **Selected Systems** and then click the left-arrow button to move it back under **Select and Add Systems**.

   - **The startup system**
     - Under **Selected Systems**, check the **Startup** option next to a system name if you want the service group to startup automatically on that system.
The system order of preference

Use the up- and down-arrow buttons to the right of the **Selected Systems** table to set the order of systems in the list. To change the position of a system in the list, click the system name in the **Selected Systems** table and then click the up- or down-arrow button to move it up or down in the list.

VCS attempts to bring the service group online on the first system in the system list, unless you have selected a different system as the startup system using the **Startup** option. If the service group cannot be brought online on the first system or on the designated startup system, VCS does one of the following:

- If the first system is also the startup system, VCS attempts to bring the service group online on each remaining system in the order listed.
- If the first system and the startup system are different, VCS attempts to bring the service group online on the first system in the list. If the first system fails, VCS attempts to bring the service group online on each remaining system in the order listed.

6 In the **Resource Configuration** dialog box, specify the following details about the resources that belong to the service group and then click **Next**:

- The member resource list
  
Enter the name of any new resources that you want to add to the service group into the **Resource Name** text box. Resource names must:
  
  - Consist of only one string
  - Not contain special characters like . (period) or & (ampersand).
  - Begin with an alphabetic character.
  
  The remaining characters in the name can be letters, digits, hyphens, or underscores.

- The resource startup state
  
  If you want the resource to start in an enabled state after the service group comes online, check **Enable Resource**. Click **Add Resource** to add the resource to the **Resource List**.

- The resource attribute values or resource removal
  
  In the **Resource List** table, you can edit resource attributes or delete a resource using the buttons in the **Edit** and **Delete** columns.
  
  See “Adding a resource to a service group” on page 143.

7 If you need to link one or more resources, provide the following relationship details in the **Link/Unlink Resource** dialog box and then click **Finish**. Otherwise, click **Finish** now to exit the wizard.

- The parent resource
Use the **Parent Resource** drop-down menu to specify which resource must be brought online after the child resource.

- The child resource
  
  Use **Child Resource** list box to select which resource should be brought online first, and then click **Add Link**.

### Modifying the system list of a service group

Edit the list of systems that can host a service group. You must have the role of cluster administrator or service group administrator to modify the system list of a service group.

**To modify the system list of a service group**

1. In the **Cluster:Groups** view, in the **Groups Listing** table, click the linked name of the service group that you want to modify.
2. In the **Group:Summary** view, in the **Configuration** task panel, click **Modify System List**.
3. In the **System List Configuration** dialog box, specify the following details for the target systems and then click **Finish**. (The target systems are the systems on that can host the service group.)

- The target system names
  
  Find the system you want in the list under **Select and Add Systems**. To quickly find a specific system, click **Filter**, type a few letters of the system name, and then click **Apply**.
  
  To select a system, click the system name under **Select and Add Systems** and then click the right-arrow button to move it under **Selected Systems**. You can select one or more systems.
  
  To reject a system, click the system name under **Selected Systems** and then click the left-arrow button to move it back under **Select and Add Systems**.

- The startup system
  
  Under **Selected Systems**, check the **Startup** option next to a system name if you want the service group to startup automatically on that system.

- The system order of preference
  
  Use the up- and down-arrow buttons to the right of the **Selected Systems** table to set the order of systems in the list. To change the position of a system in the list, click the system name in the **Selected Systems** table and then click the up- or down-arrow button to move it up or down in the list.
VCS attempts to bring the service group online on the first system in the system list, unless you have selected a different system as the startup system using the Startup option. If the service group cannot be brought online on the first system or on the designated startup system, VCS does one of the following:

- If the first system is also the startup system, VCS attempts to bring the service group online on each remaining system in the order listed.
- If the first system and the startup system are different, VCS attempts to bring the service group online on the first system in the list. If the first system fails, VCS attempts to bring the service group online on each remaining system in the order listed.

Bringing a service group online

Manually put a service group into a responsive, functioning state. You must have the role of cluster operator or service group operator to bring a service group online.

You can bring a service group online on a specific system, or you can bring the service group online “anywhere.” If you select the Anywhere option, the service group is brought online on the first available system in the cluster.

**To bring a service group online with the opportunity to specify one system**

1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the offline service group that you want to bring online.
2. In the Group:Summary view, in the Operations task panel, click Online.
3. This step is necessary only if the system list for the service group has more than one member system.
   - In the Online Service Group dialog box, select the system on which to bring the service group online, or click Anywhere.
   - The system choices in this step are populated using the system list for the service group. The Anywhere option causes this task to try each system in the list until the service group is successfully brought online.
4. Click OK to confirm that you want to bring the service group online.

**To bring one or more service groups online anywhere**

1. In the Cluster:Groups view, in the Groups Listing table, check the check box preceding the line item for the offline service group that you want to bring online. Select all service groups by checking the check box at the top.
2. In the Operations task panel, click Online Anywhere.
3 In the Online Service Group(s) dialog box, click OK to confirm that you want to bring the selected service groups online on any system in the cluster. The candidate systems are members of the system list for each service group. The Online Anywhere task tries each system in a system list until every service group is successfully brought online.

Taking a service group offline

Manually put a service group into an unresponsive, nonfunctioning state. You must have the role of cluster operator or service group operator to take a service group offline.

You can take a service group offline on a specific system, or you can take the service group offline "anywhere". If you select the Anywhere option, the service group is taken offline on the first system in the cluster on which it is found.

To take a service group offline with the opportunity to specify one system

1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the online service group that you want to take offline.

2 In the Group:Summary view, in the Operations task panel, click Offline.

3 This step is necessary if only if the service group is online on more than one system. In the Offline Service Group dialog box, select the system on which to take the service group offline, or click Anywhere.

4 Click OK to confirm that you want to take the service group offline.

To take one or more service groups offline anywhere

1 In the Cluster:Groups view, in the Clusters Listing table, check the check box preceding the line item for each online service group that you want to take offline. Select all service groups by checking the check box at the top.

2 In the Operations task panel, click Offline Anywhere.

3 In the Offline Service Group(s) dialog box, click OK to confirm that you want to take the selected service groups offline anywhere (on any system) in the cluster.
Switching a service group

Manually switch a service group to another system in the cluster.

To switch a service group
1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the service group that you want to switch.
2. In the Group:Summary view, in the Operations task panel, click Switch.
3. In the Switch Service Group dialog box, select the destination system for the service group from the drop-down menu. Select Anywhere to switch the service group to any other system in the cluster. The system choices in this step are populated using the system list for the service group. The Anywhere option causes this task to try every other system in the list until the service group is successfully brought online.
4. If insufficient room exists on the target system, you can check the Evacuate lower-priority service groups option. This option makes room for the service group being switched by taking lower-priority service groups offline.
5. Click OK.

Freezing a service group

Prevent a service group from failing over to another system. Freezing a service group stops all online and offline operations on the service group. Note that you cannot freeze a service group when the service group state is in transition.

To freeze a service group
1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the service group that you want to freeze.
2. In the Group:Summary view, in the Operations task panel, click Freeze.
3. In the Freeze Service Group dialog box, click OK to confirm that you want to freeze the specified service group. If you want the service group to remain frozen until explicitly unfrozen, check the Freeze Persistently option. Otherwise, the service group unfreezes when either the management server or the Cluster Management Console is restarted.

To freeze one or more service groups
1. In the Cluster:Groups view, in the Groups Listing table, check the check box preceding the line item for each unfrozen service group that you want to freeze. Select all service groups by checking the check box at the top.
2. In the Operations task panel, click Freeze.
3 In the Freeze Service Group(s) dialog box, click OK to confirm that you want to freeze the specified service groups.

Unfreezing a service group

Return a frozen service group to normal failover behavior. Unfreezing a service group restarts online and offline operations on the service group.

To unfreeze a service group
1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the frozen service group that you want to unfreeze.
2 In the Group:Summary view, in the Operations task panel, click Unfreeze.
3 In the Unfreeze Service Group dialog box, click OK to confirm that you want to unfreeze the specified service group.

To unfreeze one or more service groups
1 In the Cluster:Groups view, in the Groups Listing table, check the check box preceding the line item for each frozen service group that you want to unfreeze. Select all service groups by checking the check box at the top.
2 In the Operations task panel, click Unfreeze.
3 In the Unfreeze Service Group(s) dialog box, click OK to confirm that you want to unfreeze the specified service groups.

Enabling a service group

Enable a disabled service group so that it can be brought online. A service group that is manually disabled during a maintenance procedure must first be enabled before it can be brought online.

To enable a service group
1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the service group that you want to enable.
2 In the Group:Summary view, in the Operations task panel, click Enable.
3 In the Enable Service Group dialog box, use the drop-down menu to select a system on which to enable the service group. Select all to enable the service group on all systems in the cluster.
4 Click OK.
Disabling a service group

Disable a service group to prevent it from coming online. Use disablement to temporarily prevent agents from monitoring a service group on a system undergoing maintenance operations.

To disable a service group
1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the enabled service group that you want to disable.
2 In the Group:Summary view, in the Operations task panel, click Disable.
3 In the Disable Service Group dialog box, use the drop-down menu to select a system on which to disable the service group. Select all to disable the service group on all systems in the cluster.
4 Click OK.

Linking service groups

Create dependencies among service groups.
See “About service group dependencies” on page 518.

To link two service groups with a parent-child dependency
1 In the Cluster:Groups view, in the Configuration task panel, click Link Service Groups.
2 In the Link Service Groups dialog box, specify the following details of the dependency and then click OK:
   - The service groups that you intend to serve as the parent service group and the child service group
     Use the corresponding drop-down menus for this specification.
   - The relationship type
     In a Local dependency, an instance of the parent service group depends on an instance of the child service group being online or offline on the same system, depending on the category of group dependency. In a Global dependency, an instance of the parent service group depends on one or more instances of the child service group being online on any system.
   - The dependency category
     In a Soft dependency, VCS imposes minimal constraints while bringing the parent and child service groups online and taking them offline. In a Firm dependency, VCS takes the child service group offline before taking the parent service group offline when the child service group...
faults. In a **Hard** dependency, VCS takes the parent service group offline before taking the child service group offline when the child service group faults.

Hard dependencies are designed for use with Veritas Volume Replicator in disaster recovery configurations. In these configurations, the application is in the parent service group and the replication resources are in the child service group.

### Viewing service group dependencies

View a graphical representation of dependencies that exist among service groups.

View a graphical representation of dependencies that exist among service groups.

**To view service group dependencies and get status information**

1. On the navigation bar, click **[Cluster]**.
2. On the secondary tab bar, click **Summary** and then click **Group Dependency**.
   
   This view presents a graphical representation of all currently configured service groups and the dependencies that exist among them.
3. Click a service group icon to get information about the service group that it represents.

### Unlinking service groups

Remove dependencies among service groups.

**To unlink two service groups that share a parent-child dependency**

1. In the **Cluster:Groups** view, in the **Configuration** task panel, click **Unlink Service Groups**.
2. In the **Unlink Service Groups** dialog box, select the parent group and the child group from the corresponding drop-down menus and then click **OK**.

### Adding systems to a service group

Add systems to the system list of a service group. You can add systems to the system list of a service group when you add or modify the service groups in a cluster. You add or modify service groups using the Service Group Configuration wizard.

See “Adding a service group to a cluster” on page 125.

See “Modifying a service group” on page 128.
Deleting systems from a service group

Delete systems from the system list of a service group. You can delete systems from the system list of a service group when you add or modify the service groups in a cluster. You add or modify service groups using the Service Group Configuration wizard.

See “Adding a service group to a cluster” on page 125.
See “Modifying a service group” on page 128.

Faulting a service group

Manually simulate a fault on a service group to test failover behavior. This operation is available only when using the cluster simulator.

To fault a single service group

1 In the Cluster:Groups view, in the Groups Listing table, click the linked name of the service group that you want to fault.

2 In the Group:Summary view, in the Simulation task panel, click Fault Service Group.

3 In the Fault Service Group dialog box, select the systems on which you want to fault the service group from the drop-down menu. This drop-down menu is populated using the system list of the service group. The system list of a service group contains a list of all systems on which the service group is configured.

4 Click OK.

To fault one or more service groups

1 In the Cluster:Groups view, in the Groups Listing table, check the check box preceding the line item for each service group that you want to fault. Select all service groups by checking the check box at the top.

2 In the Simulation task panel, click Fault Service Groups. In the Fault Service Group(s) dialog box, use the appropriate drop-down menu to select the systems on which you want to fault each service group. Each drop-down menu is populated using the system list of each service group. The system list of a service group contains a list of all systems on which the service group is configured.

3 Click OK.
Clearing a faulted service group

Clear a service group to remove the resource faults within the group. You must have the role of cluster administrator or service group administrator to clear a faulted service group.

This task makes the service group available to be brought online. A resource fault in a service group may occur in several situations, such as a power failure or faulty configuration.

To clear a faulted service group

1. In the Group:Summary view, in the Operations task panel, click Clear Fault.
2. In the Clear Faulted Group dialog box, use the drop-down menu to select the system on which to clear the service group. To clear the group on all systems, click All Systems.
3. Click OK.

To clear one or more service groups

1. In the Cluster:Groups view, in the Groups Listing table, check the check box preceding the line item for each service group that you want to clear. Select all service groups by checking the check box at the top.
2. In the Operations task panel, click Clear Fault.
   In the Clear Service Group(s) Faults dialog box, use the appropriate drop-down menu to select the systems on which you want to clear each service group. Each drop-down menu is populated using the system list of each service group. The system list of a service group contains a list of all systems on which the service group is configured.
3. Click OK.

Modifying service group attributes

Edit the attributes of a service group. You must have the role of cluster administrator or service group administrator to edit attributes.

To edit a service group attribute using the attribute table

1. In the Group:Summary view, click Attributes.
2. In the All attributes for group table, locate the line item for the attribute you want to edit.
3. In the Edit column, click the ... (edit) button.
4. In the Edit Attribute dialog box, specify the following attribute details and then click OK:
Administering the cluster from the Cluster Management Console

Administering service groups

The attribute value

In the **Values** field, either click a value to change the it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value.

You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.

The systems on which to change the attribute

Specify a setting for the **Apply value to** option. **Apply to all nodes** applies the changes to all systems listed the **System List**, which lists all systems on which the attribute is configured. **Apply to selected nodes** enables you to select nodes from the **System List**.

To edit a service group attribute using the task pane

1. In the **Cluster:Summary** view, in the **Groups Listing** table, check the check box preceding the line item for each service group with the attribute that you want to edit. Select all service groups by checking the check box at the top.

2. In the **Configuration** task panel, click **Edit Attribute**.

3. Specify the attribute details.

   See “Modifying service group attributes” on page 138.

Flush a service group

Postpone the resolution of resource-related problems that occur while a service group is being brought online or taken offline. You must have the role of cluster administrator or service group administrator, or service group operator to flush a service group.

Flushing a service group halts the current operation on the resources yet to be brought online or taken offline. Flushing a service group typically leaves the cluster in a partial state. After flushing a service group, you can resolve the issue with the problematic resource.

To flush a service group

1. In the **Group:Summary** view, in the **Operations** task panel, click **Flush**.

2. In the **Flush Service Group** dialog box, select the system on which you want to flush the service group from the drop-down menu.

   The menu is populated with system from the service group system list, which contains the systems on which the service group is configured.

3. Click **OK**.
Adding a RemoteGroup resource from Cluster Management Console

A RemoteGroup resource enables you to monitor and manage a service group on a remote cluster. You must have the role of cluster administrator or service group administrator to configure a remote group resource.

Use the RemoteGroup agent to create a dependency between a local and remote service group. Typically, the RemoteGroup resource depends on an IP resource in the local service group.

See the *Veritas Cluster Server Bundled Agents Reference Guide* for more information on this agent.

**Note:** Although this topic refers to a remote service group, the Add Remote Group task is not part of VCS global cluster configuration. This task is intended to provide a simple way to monitor and manage a service group on another cluster.

To configure a remote group resource on a local cluster

1. In the **Group:Summary** view, in the **Configuration** task panel, click **Add Remote Group Resource**.
2. In the **Remote Group Resource** wizard, read the introductory information and then click **Next**.
3. In the **RemoteGroup Resource** dialog box, enter a name in the **RemoteGroup Resource Name** box and then click **Next**.
4. In the **Remote Cluster Authentication** dialog box, enter the host IP address and all of the required user authentication information. If you are logging in to a cluster running in secure mode, check **Select to enter domain name for Secure Cluster** and then enter the domain name in the box provided.
5. In the **Create RemoteGroup Resource** dialog box, specify the following monitoring details and then click **Finish**:
   - The remote service group
     Select the remote service group from the **Remote Service Group** drop-down menu. This menu is populated using the service groups configured in the remote cluster that you specified.
   - The type of monitoring you want to perform.
     The following options are available on the **Type of Monitoring** drop-down menu:
■ **OnlineOnly**
The RemoteGroup resource only brings the remote service group online. The RemoteGroup resource cannot take the remote service group offline.

■ **MonitorOnly**
The RemoteGroup resource only monitors the state of the remote service group. The RemoteGroup resource cannot online or offline the remote service group.

■ **OnOff**
The RemoteGroup resource brings the remote service group online or takes it offline.

■ **Monitoring details**
The **System Based Monitoring Details** setting has two options, **Any** and **One-to-One Mapping**. See the *Veritas Cluster Server Bundled Agents Reference Guide* for information on this setting.

After you configure the RemoteGroup resource, you can view the service group dependency in the Cluster:Group Dependency view.

See "Viewing service group dependencies" on page 136.
Administering resources

The Cluster Management Console enables you to add and configure resources according to the requirements of the service groups that the resource supports. Use the following views to administer a resource:

- **Cluster:Resources**
  This is a cluster-level view of all resources in the cluster.

- **Resource:Summary**
  This is the first view at the resource level in the Cluster Management Console.

- **Group:Summary**
  This is the first view at the service group level in the Cluster Management Console.

- **Group:Resources**
  This is a service-group-level view of all resources in a service group and any dependencies that exist among them.

**To navigate to the Cluster:Resources view**

1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary and then click Resources.
   In the **Cluster:Resources** view, the **Resources Listing** table lists all resources in the selected cluster. The task panels contain tasks that you can perform in a one-to-many fashion on the listed resources.

**To navigate to the Resource:Summary view**

1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary and then click Resources.
3. In the **Cluster:Resources** view, in the **Resources Listing** table, click a linked resource name.
   In the **Resource:Summary** view, you can choose a task from the task pane or select another resource-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering a single resource.

**To navigate to the Group:Summary view**

1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Summary and then click Groups.
In the **Cluster:Groups** view, in the **Service Groups Listing** table, click a linked service group name.

In the **Group:Summary** view, the **Configuration** task panel contains several resource-related tasks.

**To navigate to the Group:Resources view**

1. On the navigation bar, click **[Cluster]**.
2. On the secondary tab bar, click **Summary** and then click **Groups**.
3. In the **Cluster:Groups** view, in the **Service Groups Listing** table, click a linked service group name.
4. In the **Group:Summary** view, on the secondary tab bar, click **Resources**.

The **Group:Resources** view contains a graphical representation of the resources in the service group and any dependencies that exist among them.

### Adding a resource to a service group

Add and configure a required resource as a member of a service group. You must have the role of cluster administrator or service group administrator to add a resource to a service group.

**To add a resource to a service group**

1. In the **Group:Summary** view, in the **Configuration** task panel, click **Add/Modify Resource**.
2. In the **Resource Configuration** dialog box, specify the following details about the resource and the service group and then click **OK**:
   - The resource name
     Enter the name of the resource that you want to add to the service group into the **Resource Name** text box. Names must consist of only one string and must not contain special characters like . (period) or _ (underscore).
   - The resource type
     Select the type of the new resource from the **Resource Type** drop-down menu.
   - The resource startup state
     If you want the resource to start in an enabled state after the service group comes online, check **Enable Resource**.
Administering the cluster from the Cluster Management Console

Administering resources

- The resource list for the service group
  Click Add Resource to add the resource to the member resource list for the service group. The resource list is used to populate the Resource List table.
  In the Resource List table, you can edit resource attributes or delete a resource using the buttons in the Edit and Delete columns.

Overriding resource attributes

Change the default value of one or more resource attributes. You must have the role of cluster administrator or group administrator to override resource attribute values.

To override resource attributes

1. In the Cluster:Resources view, in the Resources Listing table, click a linked resource name.
2. In the Resource:Summary view, in the Configuration task panel, click Override Attributes.
3. In the Override Attributes dialog box, select the attribute you want to override from the drop-down menu and then click OK.
4. In the Edit Attribute dialog box, specify the following attribute details and then click OK:
   - The attribute value
     In the Values field, either click a value to change the it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value.
     You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.
   - The systems on which to change the attribute
     Specify a setting for the Apply value to option. Apply to all nodes applies the changes to all systems listed the System List, which lists all systems on which the attribute is configured. Apply to selected nodes enables you to select nodes from the System List.

To remove resource overrides

1. In the Cluster:Resources view, in the Resources Listing table, click a linked resource name.
2. In the Resource:Summary view, in the Configuration task panel, click Remove Overrides.
3 Click **OK** to confirm that you want to remove previously configured override values.

**Enabling and disabling resources**

Prepare a resource to be brought online or prevent a resource from being brought online. A resource must be enabled before it can be brought online. A disabled resource cannot be brought online. You must have the role of cluster operator or service group operator to enable or disable resources.

**To enable or disable selected resources**

1 In the **Cluster:Resources** view, in the **Resources Listing** table, click a linked resource name.

2 In the **Operations** task panel, click **Enable** or **Disable**.

3 In either the **Enable Resource** or **Disable Resource** dialog box, click **OK**.

**Bringing a resource online**

Manually bring a resource online. You must have the role of cluster operator or group operator to bring a resource online.

1 In the **Cluster:Resources** view, in the **Resources Listing** table, click the linked name of the resource you want to bring online.

2 In the **Resource:Summary** view, in the **Operations** task panel, click **Online**.

3 In the **Online Resource** dialog box, select the system on which to bring the resource online from the drop-down menu.

4 Click **OK**.

**Taking a resource offline**

Manually take a resource offline. You must have the role of cluster operator or group operator to take a resource online.

1 In the **Cluster:Resources** view, in the **Resources Listing** table, click the linked name of the resource you want to bring online.

2 In the **Resource:Summary** view, in the **Operations** task panel, click **Online**.

3 In the **Online Resource** dialog box, select the system on which to bring the resource online from the drop-down menu.

4 Click **OK**.
Taking a resource offline and propagating the command

Take a resource and all of its dependents offline. Use this task to propagate the offline state of a parent resource to its child resources. This link is disabled if any of the following conditions exist:

- You do not have the role of either cluster administrator or cluster operator
- The resource does not depend on any other resource
- An online resource depends on this resource
- The resource is not online

To take a parent resource and all of its child resources offline

1. In the Cluster:Resources view, in the Resources Listing table, click the linked name of the resource you want to take offline.
2. In the Resource:Summary view, in the Operations task panel, click Offline Propagate.
3. In the Offline Propagate for Resource dialog box, select the system on which to bring the resource online from the drop-down menu.
4. Click OK.

Faulting a resource

Manually simulate a fault on a resource to test failover behavior. This operation is available only when using the cluster simulator.

To fault a single service group

1. In the Cluster:Resources view, in the Resources Listing table, click the linked name of the resource that you want to fault.
2. In the Resource:Summary view, in the Simulation task panel, click Fault Resource.
3. In the Fault Resource dialog box, on the drop-down menu, select the systems on which you want to fault the resource. This drop-down menu is populated using the system list of the resource. The system list of a resource contains a list of all systems on which the resource is configured.
4. Click OK.
To fault one or more resources

1. In the Cluster:Resources view, in the Resources Listing table, check the check box preceding the line item for each resource that you want to fault. Select all resources by checking the check box at the top.

2. In the Simulation task panel, click Fault Resources.
   In the Fault Resource(s) dialog box, use the appropriate drop-down menu to select the systems on which you want to fault each resource. Each drop-down menu is populated using the system list of each resource. The system list of a resource contains a list of all systems on which the resource is configured.

3. Click OK.

Clearing a faulted resource

Clear a resource to remove a fault and make the resource available to go online. You must have the role of cluster operator or service group operator to clear a faulted resource. A resource fault can result from occurrences such as a power failure or a faulty configuration.

To clear a single faulted resource

1. In the Cluster:Resources view, in the Resources Listing table, click the linked name of the faulted resource that you want to clear.

2. In the Resource:Summary view, in the Operations task panel, click Clear Fault.

To clear one or more faulted resources

1. In the Cluster:Resources view, in the Resources Listing table, check the check box preceding the line item for each resource that you want to clear. Select all resources by checking the check box at the top.

2. In the Operations task panel, click Clear Fault.

Probing a resource

Probe a resource to confirm that it is properly configured and ready to bring online.

To probe a resource

1. In the Cluster:Resources view, in the Resources Listing table, click the linked name of the resource that you want to probe.

2. In the Resource:Summary view, in the Operations task panel, click Probe.
3. In the Probe Resource dialog box, select the system on which you want to probe the specified resource from the drop-down menu and then click OK. The dialog box displays a message indicating success or failure. Success indicates that the resource is properly configured and, if not already online, is ready to be brought online.

Deleting a resource from a service group

Delete a resource from membership in a service group. You must have the role of cluster administrator or service group administrator to delete a resource from a service group.

To delete a resource from a service group

1. In either the Cluster:Resources or Group:Summary view, in the Resource Listing table, click the linked name of the resource that you want to delete.
2. In the Resource:Summary view, in the Configuration task panel, click Delete Resource.
3. In the Delete Resource dialog box, click OK to confirm that you want to delete the resource.

Linking resources

Link resources to create a dependency. You must have the role of cluster administrator or service group administrator to link resources.

To link two resources

1. In the Resource:Summary view, in the Configuration task panel, click Link/Unlink Resource.
2. In the Link/Unlink Resource dialog box, specify the following details for the resource link and then click OK:
   - The parent resource
     Select the parent resource from the drop-down menu. This resource must be brought online before the child resource. The Parent Resource menu is populated using the resource list of the service group in which the resources are configured.
   - The child resource
     Select the child resource from the scroll box. This resource is brought online after the parent resource. The Child Resource scroll box is populated using the resource list of the service group in which the resources are configured. This list is filtered depending upon the
Administering the cluster from the Cluster Management Console

Administering resources

selection you make in Parent Resource. Click Add Link after you select a child resource to add the link to the Currently Linked table.

Viewing resource dependencies

View a graphical representation of the dependencies that exist for a resource.

To view service group dependencies and get status information
1 On the navigation bar, click [Cluster].
2 On the secondary tab bar, click Summary and then click Resources.
3 In the Resources Listing table, click the linked name of a resource.
4 In the Resource:Summary view, on the secondary tab bar, click Dependency. This view presents a graphical representation of the selected resource and all currently configured resources that have a dependency relationship with the resource.
5 Click a resource icon to get information about the resource that it represents.

Unlinking resources

Unlink two resources to remove a dependency. You must have the role of cluster administrator or service group administrator to unlink resources.

To unlink two resources
1 In the Resource:Summary view, in the Configuration task panel, click Link/Unlink Resource.
2 In the Link/Unlink Resource dialog box, in the Currently Linked table, click the X button on the line item that corresponds to the link that you want to remove.
3 Click OK.

Modifying a resource attribute

Edit the attributes of a resource. You must have the role of cluster administrator or service group administrator to edit resource attributes.

To edit a resource attribute using the attribute table
1 In the Resource:Summary view, on the secondary tab bar, click Attributes.
2 In the All attributes for resource table, locate the line item for the attribute you want to edit.
3 In the Edit column, click the ... (edit) button.

4 In the Edit Attribute dialog box, specify the following attribute details and then click OK:
   ■ The attribute value
     In the Values field, either click a value to change the it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value.
     You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.
   ■ The systems on which to change the attribute
     Specify a setting for the Apply value to option. Apply to all nodes applies the changes to all systems listed the System List, which lists all systems on which the attribute is configured. Apply to selected nodes enables you to select nodes from the System List.

Invoking a resource action

Run a predefined action script on a resource. Examples of predefined resource actions include splitting and joining disk groups.

To invoke a resource action
1 In the Cluster:Resources view, in the Resources Listing table, click the linked name of the resource on which you want to invoke an action.

2 In the Resource:Summary view, in the Operations task panel, click Invoke Action.

3 In the Invoke Action dialog box, select the script that you want to run and the system on which you want to run it.

4 Specify arguments for the action
   Click the + (plus) button to add arguments. Click an argument name and then click the – (minus) button to remove it.

5 Click OK.

Refreshing the ResourceInfo attribute

Refresh the ResourceInfo attribute to view the latest values for that attribute.

To refresh the ResourceInfo attribute
1 In the Cluster:Resources view, in the Resources Listing table, click the linked name of a resource with the ResourceInfo attribute.
2 In the **Resource:Summary** view, in the **Operations** task panel, click **Refresh Resource Info**.

3 In the **Refresh Resource Info** dialog box, select the system on which you want to refresh the ResourceInfo attribute.

4 Click **OK**.

### Clearing the ResourceInfo attribute

Clear the ResourceInfo attribute to reset all the parameters in this attribute.

**To clear the parameters of the ResourceInfo attribute**

1 In the **Cluster:Resources** view, in the **Resources Listing** table, click the linked name of a resource with the ResourceInfo attribute.

2 In the **Resource:Summary** view, in the **Operations** task panel, click **Clear Resource Info**.

3 In the **Clear Resource Info** dialog box, select the system on which you want to clear the ResourceInfo attribute.
Administering resource types

The Cluster Management Console enables you to add and configure resource types according to the requirements of the resources that they represent. Use the following views to administer a resource type:

- **Cluster:Resource Types**
  This is a cluster-level view of all resource types in the cluster.

- **Resource Type:Attributes**
  This is the first and only view at the resource type level in the Cluster Management Console.

To navigate to the **Cluster:Resource Types** view

1. On the navigation bar, click **[Cluster]**.
2. On the secondary tab bar, click **Summary** and then click **Resource Types**.

   In the **Cluster:Resource Types** view, the **Resource Types Listing** table lists all resource types in the selected cluster. The task panels contain tasks that you can perform in a one-to-many fashion on the listed resource types.

To navigate to the **Resource Type:Attributes** view

1. On the navigation bar, click **[Cluster]**.
2. On the secondary tab bar, click **Summary** and then click **Resource Types**.
3. In the **Cluster:Resource Types** view, in the **Resource Types Listing** table, click a linked resource type name.

   In the **Resource Type:Attributes** view, you can choose a task from the task pane or click the button in the **Edit** column of the table to edit the attribute value.

Modifying resource type attributes

Edit the attributes of a resource type. You must have the role of cluster administrator or service group administrator to edit resource type attributes.

To edit resource type attributes using the attribute table

1. In the **Cluster:Resource Types** view, in the **Resource Types Listing** table, click a linked resource name.

2. In the **Resource Type:Attributes** view, in the **All attributes for resource type** table, locate the line item for the attribute that you want to edit. Not all attributes can be edited.

3. In the **Edit** column, click the ... (edit) button.
4 In the **Edit Attribute** dialog box, specify the following attribute details and then click **OK**:

- The attribute value
  - In the **Values** field, specify an appropriate string value for the attribute.
- The systems on which to change the attribute
  - Specify a setting for the **Apply value to** option. **Apply to all nodes** applies the changes to all systems listed the **System List**, which lists all systems on which the attribute is configured. **Apply to selected nodes** enables you to select nodes from the **System List**.
Administering systems

The Cluster Management Console enables you to configure and manage the systems that host the cluster service groups and resources. Use the Cluster:Systems view and the System:Summary view to administer systems.

To navigate to the Cluster:Systems view
1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Systems.
   In the Cluster:Systems view, the Systems Listing table lists all systems in the selected cluster. The task panels contain several tasks that you can perform in a one-to-many fashion on the listed systems.

To navigate to the System:Summary view
1. On the navigation bar, click [Cluster].
2. On the secondary tab bar, click Systems.
3. In the Cluster:Systems view, in the Systems Listing table, click a linked system name.
   In the Systems:Summary view, you can choose a task from the task pane or select another system-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering a single system.

Freezing a System

Freeze a system to prevent the service groups that it hosts from failing over to another system. Use this procedure before performing a system upgrade.

To freeze a system
1. In the [Cluster]:Systems view, in the Systems Listing table, click the linked name of the system that you want to freeze.
2. In the System:Summary view, in the Operations task panel, click Freeze.
3. In the Freeze System dialog box, select one or both of the following options:
   - Select Persistent if you want the system to retain a frozen state when the cluster is rebooted.
   - Select Evacuate if you want the system's active service groups to fail over to another system in the cluster before the freezing operation takes place.
4. Click OK.
You can freeze one or more systems at a time directly from the **Cluster:Systems** view by selecting the check boxes for systems in the **Systems Listing** table and then clicking **Freeze** in the **Operations** task panel.

### Unfreezing a system
Unfreeze a frozen system to perform online or offline operations on the system.

**To unfreeze a system**

1. In the **Cluster:Systems** view, in the **Systems Listing** table, click the linked name of the system that you want to unfreeze.
2. In the **System:Summary** view, in the **Operations** task panel, click **Unfreeze**.
3. In the **Unfreeze System** dialog box, click **OK** to confirm that you want to unfreeze the system.

You can unfreeze one or more systems at a time directly from the **Cluster:Systems** view by selecting the check boxes for systems in the **Systems Listing** table and then clicking **Unfreeze** in the **Operations** task panel.

### Modifying system attributes
Edit the attributes of a system. You must have the role of cluster administrator or service group administrator to edit system attributes.

Edit the attributes of a cluster. You must have the role of cluster administrator to edit cluster attributes.

**To edit a cluster attribute using the attribute table**

1. In the **System:Summary** view, on the secondary tab bar, click **Attributes**.
2. In the **All attributes for system** table, locate the line item for the attribute you want to edit. Not all attributes can be edited.
3. In the **Edit** column, click the ... (edit) button.
4. In the **Edit Attribute** dialog box, specify the following attribute details and then click **OK**:

   - The attribute value
     - In the **Values** field, either click a value to change the it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value.
     - You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.
The systems on which to change the attribute
Specify a setting for the **Apply value to** option. **Apply to all nodes**
applies the changes to all systems listed in the **System List**, which lists all
systems on which the attribute is configured. **Apply to selected nodes**
enables you to select nodes from the **System List**.

**To edit a system attribute using the task pane**

1. In the **Cluster:Summary** view, in the **Clusters Listing** table, check the check box preceding the line item for each system with the attribute that you want
to edit. Select all systems by checking the check box at the top.

2. In the **Configuration** task panel, click **Edit Attribute**.

3. Specify the attribute details.
   See “To edit a system attribute using the attribute table” in “Modifying
system attributes” on page 155.
Administering attributes

The Cluster Management Console enables you to edit the attributes of cluster objects (clusters, service groups, systems, resources, and resource types). Ensure that the cluster configuration is open (in read/write mode) before editing attributes. Attributes for an object are available in any object summary view, such as the Cluster:Summary view or the Resource:Summary view. After navigating to an object summary view, click the Attributes tab on the secondary tab bar.

Changes to certain attributes, such as a webip attribute, may involve taking the service group offline, modifying the configuration file, and bringing the group back online.

To edit an attribute

1. Navigate to an Object:Summary view for the object with the attributes you want to edit.
   See “Overview of the Cluster Management Console” on page 110 for information about navigating among views in the view hierarchy.

2. In the Object:Summary view, on the secondary tab bar, click Attributes.

3. In the All attributes table, click the ... (edit) button for the attribute you want to edit.

4. In the Edit Attribute dialog box, specify the following attribute details and then click OK:
   - The attribute value
     In the Values field, either click a value to change the it, or click the + (plus) button to add a value. Click a value and then click the - (minus) button to remove a value. (Some Edit Attribute dialog boxes have just a text field for the value).
     You can enter more than one value for some attributes. Use the up- and down-arrow buttons to scroll among multiple values.
   - The systems on which to change the attribute
     Specify a setting for the Apply value to option. Apply to all nodes applies the changes to all systems listed the System List, which lists all systems on which the attribute is configured. Apply to selected nodes enables you to select nodes from the System List.
Viewing logs

In the Manage tab view hierarchy, the following levels of views each have a logs tab on the secondary tab bar.

- Cluster
- Group
- System
- Resource

See “The Manage tab, secondary tabs, and the view hierarchy” on page 113.

The Logs tab takes you to a view of log entries about the individual object that you select.

To navigate to the logs view for an object

1. On the navigation bar, click Manage.
2. Navigate to one of the following views for a particular object:
   - **Cluster:Summary**
   - **Group:Summary**
   - **System:Summary**
   - **Resource:Summary**
3. In the **Object:Summary** view, on the secondary tab bar, click Logs.

   **Object** is the type of the object that you selected. Each logs tab contains a search box and Search button so that you can quickly find the log entries that you want.

See “Overview of the Cluster Management Console” on page 110 for information about navigating among views.

See “Conducting a search” on page 159.

**Note:** Logs for clusters and service groups contain entries about only the object that you select. Entries for descendant objects are not included.
Conducting a search

You can perform a search using either the search bar or the Search tab.

The search bar is located immediately below the main tab bar, and contains a text entry box and a Search button. (You may need to scroll right to see these controls on some systems.) The search bar is available for all views except those under the Search tab.

The Search tab is located on the main tab bar. Views under the Search tab contain a text entry box and a Search button and offer some filtering options.

The search feature displays results in one or more of the search views, which you navigate to using secondary tabs under Search. These tabs are labelled Clusters, Groups, Systems, Resources, Resource Types, and Logs. Each tab contains a table that lists the search results, or hits, in the corresponding object category. By default, the console takes you to the search views after each search. The destination view is whichever view was most recently visited.

The search feature supports a form of Boolean AND and OR operations, as well as "wildcard" searches, with the Exact Match and Match All Terms options. The search feature does not currently support:

To perform a search using the search bar
1. In the text entry box, type one or more text strings that you want to find. Use a space character to separate text strings.
2. Click Search.
3. Visit each search view to see the hits in each object category. Your particular destination view depends on which search view was most recently visited. Click the other secondary tabs (Clusters, Groups, and so on) to visit the other search views.

To perform a search using the Search tab
1. On the main tab bar, click Search.
2. On the secondary tab bar, click the object category (Clusters, Groups, and so on) in which you want to begin your search.
3. In the text entry box, type one or more text strings that you want to find. Use a space character to separate text strings.
4. Check one or more of the following options and then click Search:
   - **Exact Match**
     Requires each search result to match at least one whole search string. This option excludes occurrences in which a search string is part of a longer string.
- **Match All Terms**
  Requires each search result to match all search terms (strings).
  The behavior of this option depends on the setting of the **Exact Match** option according to the following example:
  Consider object1 with attribute `path = /tmp/f3` and object2 with attribute `path = /tmp/f4`:

<table>
<thead>
<tr>
<th>Search String</th>
<th>Exact Match Option Setting</th>
<th>Match All Terms Option Setting</th>
<th>Search results</th>
</tr>
</thead>
<tbody>
<tr>
<td>path f3</td>
<td>checked</td>
<td>checked</td>
<td>none</td>
</tr>
<tr>
<td>path f3</td>
<td>checked</td>
<td>cleared</td>
<td>none</td>
</tr>
<tr>
<td>path f3</td>
<td>cleared</td>
<td>checked</td>
<td>object1</td>
</tr>
<tr>
<td>path f3</td>
<td>cleared</td>
<td>cleared</td>
<td>object1, object2</td>
</tr>
</tbody>
</table>

- **Highlight**
  Highlights the string occurrences in the search result tables.
  Combine **Exact Match** and **Match All Terms** to minimize the number of candidate occurrences.

5. Visit each search view to see the hits in each object category.
   Your first results are displayed in the same view in which you started the search. Click the other secondary tabs (**Clusters**, **Groups**, and so on) to see any hits the other search views.

**Note:** After you perform a search, changing the Exact Match, Match All Terms, and Highlight option settings automatically updates the results.
Administering the cluster from Cluster Manager (Java console)

- Administering VCS Simulator
About the Cluster Manager (Java Console)

Cluster Manager (Java Console) offers complete administration capabilities for your cluster. Use the different views in the Java Console to monitor clusters and VCS objects, including service groups, systems, resources, and resource types. Many of the operations supported by the Java Console are also supported by the command line interface and Cluster Management Console.

The console enables or disables features depending on whether the features are supported in the cluster that the console is connected to. For example, the Cluster Shell icon is grayed out when you connect to recent versions of VCS. But the icon is enabled when you connect to earlier versions of a VCS cluster.

Symantec also offers the Veritas Cluster Server (VCS) Management Console to manage clusters. Refer to the Veritas Cluster Server Management Console Implementation Guide for installation, upgrade, and configuration instructions.

To download the most current version of VCS Management Console, go to http://go.symantec.com/vcsmc.

Getting started

- Make sure you have the current version of Cluster Manager (Java Console) installed. If you have a previous version installed, upgrade to the latest version. Cluster Manager (Java Console) is compatible with earlier versions of VCS.

- Cluster Manager (Java Console) is supported on:
  - Windows XP and Windows 2003

If you have configured Windows Firewall, add ports 14141 and 14150 to the Exceptions list.

Refer to the Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide for a list of SFW HA services and ports used.

*Note:* Make sure you are using an operating system version that supports JRE 1.5.

- Verify the configuration has a user account. A user account is established during VCS installation that provides immediate access to Cluster Manager. If a user account does not exist, you must create one.
  See “Adding a user” on page 197.

- Start Cluster Manager.
  See “Starting Cluster Manager (Java Console)” on page 163.
Add a cluster panel.
See “Configuring a new cluster panel” on page 192.

- Log on to a cluster.
  See “Logging on to and off of a cluster” on page 194.

- Make sure you have adequate privileges to perform cluster operations.
  See “About the VCS user privilege model” on page 67.

Starting Cluster Manager (Java Console)

To start the Java Console on Windows systems
From the Start menu, click Start>All Programs>Symantec>Veritas Cluster
Server>Veritas Cluster Manager - Java Console.

Reviewing components of the Java Console

Cluster Manager (Java Console) offers two windows, Cluster Monitor and Cluster
Explorer, from which most tasks are performed. Use Cluster Manager to
manage, configure, and administer the cluster while VCS is running (online).
The Java Console also enables you to use VCS Simulator. Use this tool to
simulate operations and generate new configuration files (main.cf and types.cf)
while VCS is offline. VCS Simulator enables you to design configurations that
imitate real-life scenarios without test clusters or changes to existing
configurations.
See “Administering VCS Simulator” on page 257.

Icons in the Java Console

The Java Console uses the following icons to communicate information about
cluster objects and their states.
See “Cluster and system states” on page 737.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Cluster icon" /></td>
<td>Cluster</td>
</tr>
</tbody>
</table>
### Table 7-1  Icons in Cluster Manager (Java Console)

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>

<td></td>
<td>Remote Cluster in <strong>EXITING, EXITED, INIT, INQUIRY, LOST_CONN, LOST_HB, TRANSITIONING, or UNKNOWN</strong> state.</td>
</tr>
</tbody>
</table>
About Cluster Monitor

After starting Cluster Manager, the first window that appears is Cluster Monitor. This window includes one or more panels displaying general information about actual or simulated clusters. Use Cluster Monitor to log on to and off of a cluster, view summary information on various VCS objects, customize the display, use VCS Simulator, and exit Cluster Manager.

Cluster monitor toolbar

The Cluster Monitor toolbar contains the following buttons.

* **New Cluster.** Adds a new cluster panel to Cluster Monitor.

* **Delete Cluster.** Removes a cluster panel from Cluster Monitor.

* **Expand.** Expands the Cluster Monitor view.

* **Collapse.** Collapses the Cluster Monitor view.
Administering the cluster from Cluster Manager (Java console)

About Cluster Monitor

Stop. Pauses cluster panel scrolling.

Start. Resumes scrolling.

Login. Log on to the cluster shown in the cluster panel.

Show Explorer. Launches an additional window of Cluster Explorer after logging on to that cluster.

Move Cluster Panel Up. Moves the selected cluster panel up.

Move Cluster Panel Down. Moves the selected cluster panel down.

Help. Access online help.
Cluster monitor panels

To administer a cluster, add a cluster panel or reconfigure an existing cluster panel in Cluster Monitor. Each panel summarizes the status of the connection and components of a cluster.

Monitoring the cluster connection with Cluster Monitor

The right pane of a panel in Cluster Monitor displays the status of the connection to a cluster. An inactive panel will appear grey until the user logs on and connects to the cluster. To alter the connection to a cluster, right-click a panel to access a menu.

- The menu on an active panel enables you to log off a cluster.
- The menu on an inactive panel enables you to log on to a cluster, configure the cluster, and delete the cluster from Cluster Monitor.

Menus are enabled when the Cluster Monitor display appears in the default expanded view. If you activate a menu on a collapsed scrolling view of Cluster Monitor, the scrolling stops while accessing the menu.

If the system to which the console is connected goes down, a message notifies you that the connection to the cluster is lost. Cluster Monitor tries to connect to another system in the cluster according to the number of Failover retries set in the Connectivity Configuration dialog box. The panels flash until Cluster Monitor is successfully connected to a different system. If the failover is unsuccessful, a message notifies you of the failure and the panels turn grey.

Monitoring VCS objects with Cluster Monitor

Cluster Monitor summarizes the state of various objects in a cluster and provides access to in-depth information about these objects in Cluster Explorer. The right pane of a Cluster Monitor panel displays the connection status (online, offline, up, or down) of service groups, systems, and heartbeats. The left pane of a Cluster Monitor panel displays three icons representing service groups, systems, and heartbeats. The colors of the icons indicate the state of the cluster; for example:

- A flashing red slash indicates Cluster Manager failed to connect to the cluster and will attempt to connect to another system in the cluster.
- A flashing yellow slash indicates Cluster Manager is experiencing problems with the connection to the cluster.

Pointing to an icon accesses the icon’s ScreenTip, which provides additional information on the specific VCS object.
To review detailed information about VCS objects in Cluster Explorer, Logs, and Command Center, right-click a panel to access a menu. Menus are enabled when the Cluster Monitor display appears in the default expanded view. If you activate a menu on a collapsed scrolling view of Cluster Monitor, the scrolling stops while accessing the menu.

Expanding and collapsing the Cluster Monitor display

Cluster Monitor supports two views: expanded (default) and collapsed. The expanded view shows all cluster panels. The collapsed view shows one cluster panel at a time as the panels scroll upward.

Operations enabled for the expanded view of cluster panels, such as viewing menus, are also enabled on the collapsed view after the panels stop scrolling.

To collapse the Cluster Monitor view

On the View menu, click Collapse.

or

Click Collapse on the Cluster Monitor toolbar.

To expand the Cluster Monitor view

On the View menu, click Expand.

or

Click Expand on the Cluster Monitor toolbar.

To pause a scrolling cluster panel

Click the cluster panel.

or

Click Stop on the Cluster Monitor toolbar.
Customizing the Cluster Manager display

Customize the Cluster Manager to display objects according to your preference.

To customize the Cluster Manager display

1. From Cluster Monitor, click Preferences on the File menu. If you are using a Windows system, proceed to step 2. Otherwise, proceed to step 3.

2. In the Look & Feel tab (for Windows systems):
   - Click Native (Windows or Motif) look & feel or Java (Metal) look & feel.
   - Click Apply.

3. In the Appearance tab:
   - Click the color (applies to Java (Metal) look & feel).
   - Click an icon size.
   - Select the Show Tooltips check box to enable ToolTips.
   - Select the Remove Cluster Manager colors check box to alter the standard color scheme.
   - Click Apply.
4 In the **Sound** tab:

![Sound configuration window](image)

**Note:** This tab requires a properly configured sound card.

- Select the **Enable Sound** check box to associate sound with specific events.
- Click an event from the **Events** configuration tree.
- Click a sound from the **Sounds** list box.
- To test the selected sound, click **Play**.
- Click **Apply**.
- Repeat these steps to enable sound for other events.

5 After you have made your final selection, click **OK**.
About Cluster Explorer

Cluster Explorer is the main window for cluster administration. From this window, you can view the status of VCS objects and perform various operations.

The display is divided into three panes. The top pane includes a toolbar that enables you to quickly perform frequently used operations. The left pane contains a configuration tree with three tabs: Service Groups, Systems, and Resource Types. The right pane contains a panel that displays various views relevant to the object selected in the configuration tree.

To access Cluster Explorer

1. Log on to the cluster.
2. Click anywhere in the active Cluster Monitor panel.
   or
   Right-click the selected Cluster Monitor panel and click Explorer View from the menu.
Cluster Explorer toolbar

The Cluster Explorer toolbar contains 18 buttons. Available operations are described below. Note: Some buttons may be disabled depending on the type of cluster (local or global) and the privileges with which you logged on to the cluster.

From left to right:

- Open Configuration. Modifies a read-only configuration to a read-write file. This enables you to modify the configuration.
- Save Configuration. Writes the configuration to disk.
- Save and Close Configuration. Writes the configuration to disk as a read-only file.
- Add Service Group. Displays the Add Service Group dialog box.
- Add Resource. Displays the Add Resource dialog box.
- Add System. Displays the Add System dialog box.
- Manage systems for a Service Group. Displays the System Manager dialog box.
- Online Service Group. Displays the Online Service Group dialog box.
- Offline Service Group. Displays the Offline Service Group dialog box.
- Show Command Center. Enables you to perform many of the same VCS operations available from the command line.
- Show Shell Command Window. Enables you to launch a non-interactive shell command on cluster systems, and to view the results on a per-system basis.
About Cluster Explorer

Show the Logs. Displays alerts and messages received from the VCS engine, VCS agents, and commands issued from the console.

Launch Configuration Wizard. Enables you to create VCS service groups.

Launch Notifier Resource Configuration Wizard. Enables you to set up VCS event notification.

Remote Group Resource Configuration Wizard. Enables you to configure resources to monitor a service group in a remote cluster.

Add/Delete Remote Clusters. Enables you to add and remove global clusters.

Configure Global Groups. Enables you to convert a local service group to a global group, and vice versa.

Query. Enables you to search the cluster configuration according to filter criteria.

Virtual Fire Drill. Checks whether a resource can fail over to another node in the cluster. Requires agents that support running virtual fire drills.

Show Cluster Explorer Help. Enables you to access online help.
Cluster Explorer configuration tree

The Cluster Explorer configuration tree is a tabbed display of VCS objects.

- The **Service Groups** tab lists the service groups in the cluster. Expand each service group to view the group’s resource types and resources.
- The **Systems** tab lists the systems in the cluster.
- The **Types** tab lists the resource types in the cluster.

Cluster Explorer view panel

The right pane of the Cluster Explorer includes a view panel that provides detailed information about the object selected in the configuration tree. The information is presented in tabular or graphical format. Use the tabs in the view panel to access a particular view. The console enables you to “tear off” each view to appear in a separate window.

- Click any object in the configuration tree to access the Status View and Properties View.
- Click a cluster in the configuration tree to access the Service Group view, System Connectivity view, and Remote Cluster Status View (for global clusters only).
- Click a service group in the configuration tree to access the Resource view.

**To create a tear-off view**

On the **View** menu, click **Tear Off**, and click the appropriate view from the menu.

**or**

Right-click the object in the configuration tree, click **View**, and click the appropriate view from the menu.
Status view

The Status View summarizes the state of the object selected in the configuration tree. Use this view to monitor the overall status of a cluster, system, service group, resource type, and resource.

For example, if a service group is selected in the configuration tree, the Status View displays the state of the service group and its resources on member systems. It also displays the last five critical or error logs. Point to an icon in the status table to open a ScreenTip about the relevant VCS object.

For global clusters, this view displays the state of the remote clusters. For global groups, this view shows the status of the groups on both local and remote clusters.

To access the Status view

1. From Cluster Explorer, click an object in the configuration tree.
2. In the view panel, click the Status tab.
Properties view

The Properties View displays the attributes of VCS objects. These attributes describe the scope and parameters of a cluster and its components.

![Properties View](image)

To view information on an attribute, click the attribute name or the icon in the Help column of the table.

See “VCS attributes” on page 745”

By default, this view displays key attributes of the object selected in the configuration tree. The Properties View for a resource displays key attributes of the resource and attributes specific to the resource types. It also displays attributes whose values have been overridden.

See “Overriding resource type static attributes” on page 232.

To view all attributes associated with the selected VCS object, click Show all attributes.

To access the properties view

1. From Cluster Explorer, click a VCS object in the configuration tree.
2. In the view panel, click the Properties tab.
Service Group view

The Service Group view displays the service groups and their dependencies in a cluster. Use the graph and ScreenTips in this view to monitor, create, and disconnect dependencies. To view the ScreenTips, point to a group icon for information on the type and state of the group on the cluster systems, and the type of dependency between the service groups.

The line between two service groups represents a dependency, or parent-child relationship. In VCS, parent service groups depend on child service groups. A service group can function as a parent and a child.

See “About service group dependencies” on page 518.

The color of the link between service groups indicates different types of dependencies.

- A blue link indicates a soft dependency.
- A red link indicates a firm dependency.
- A green link indicates a hard dependency typically used with VVR in disaster recovery configurations.

To access the Service Group view

1. From Cluster Explorer, click a cluster in the configuration tree.
2. In the view panel, click the **Service Groups** tab.
Resource view

The Resource view displays the resources in a service group. Use the graph and ScreenTips in this view to monitor the dependencies between resources and the status of the service group on all or individual systems in a cluster.

In the graph, the line between two resources represents a dependency, or parent-child relationship. Resource dependencies specify the order in which resources are brought online and taken offline. During a failover process, the resources closest to the top of the graph must be taken offline before the resources linked to them are taken offline. Similarly, the resources that appear closest to the bottom of the graph must be brought online before the resources linked to them can come online.

- A resource that depends on other resources is a parent resource. The graph links a parent resource icon to a child resource icon below it. Root resources (resources without parents) are displayed in the top row.
- A resource on which the other resources depend is a child resource. The graph links a child resource icon to a parent resource icon above it.
- A resource can function as a parent and a child.

Point to a resource icon to display ScreenTips about the type, state, and key attributes of the resource. The state of the resource reflects the state on a specified system (local).

In the bottom pane of the Resource view, point to the system and service group icons to display ScreenTips about the service group status on all or individual systems in a cluster. Click a system icon to view the resource graph of the service group on the system. Click the service group icon to view the resource graph on all systems in the cluster.
To access the Resource view
1. From Cluster Explorer, click the service groups tab in the configuration tree.
2. Click a service group in the configuration tree.
3. In the view panel, click the Resources tab.

Moving and linking icons in Service Group and Resource views

The Link and Auto Arrange buttons are available in the top right corner of the Service Group or Resource view:

![Link and Auto Arrange buttons]

Click Link to set or disable the link mode for the Service Group and Resource views.

**Note:** There are alternative ways to set up dependency links without using the Link button.

The link mode enables you to create a dependency link by clicking on the parent icon, dragging the yellow line to the icon that will serve as the child, and then clicking the child icon. Use the Esc key to delete the yellow dependency line connecting the parent and child during the process of linking the two icons.

If the Link mode is *not* activated, click and drag an icon along a horizontal plane to move the icon. Click Auto Arrange to reset the appearance of the graph. The view resets the arrangement of icons after the addition or deletion of a resource, service group, or dependency link. Changes in the Resource and Service Group views will be maintained after the user logs off and logs on to the Java Console at a later time.
Zooming in on Service Group and Resource views

The Resource view and Service Group view include a navigator tool to zoom in or out of their graphs. Click the magnifying glass icon in the top right corner to open the zoom panel.

- To move the view to the left or right, click a distance (in pixels) from the drop-down list box between the hand icons. Click the <- or -> hand icon to move the view in the desired direction.
- To shrink or enlarge the view, click a size factor from the drop-down list box between the magnifying glass icons. Click the - or + magnifying glass icon to modify the size of the view.
- To view a segment of the graph, point to the box to the right of the + magnifying glass icon. Use the red outline in this box to encompass the appropriate segment of the graph. Click the newly outlined area to view the segment.
- To return to the original view, click the magnifying glass icon labeled 1.
System Connectivity view

The System Connectivity view displays the status of system connections in a cluster. Use this view to monitor the system links and disk group heartbeats.

VCS monitors systems and their services over a private network. The systems communicate via heartbeats over an additional private network, which enables them to recognize which systems are active members of the cluster, which are joining or leaving the cluster, and which have failed.

VCS protects against network failure by requiring that all systems be connected by two or more communication channels. When a system is down to a single heartbeat connection, VCS can no longer discriminate between the loss of a system and the loss of a network connection. This situation is referred to as jeopardy.

Point to a system icon to display a ScreenTip on the links and disk group heartbeats. If a system in the cluster is experiencing a problem connecting to other systems, the system icon changes its appearance to indicate the link is down. In this situation, a jeopardy warning may appear in the ScreenTip for this system.

To access the System Connectivity view

1. From Cluster Explorer, click a cluster in the configuration tree.
2. In the view panel, click the System Connectivity tab.
Remote Cluster Status view

**Note:** This view requires the VCS Global Cluster Option.

The Remote Cluster Status View provides an overview of the clusters and global groups in a global cluster environment. Use this view to view the name, address, and status of a cluster, and the type (icmp or icmpS) and state of a heartbeat.

This view enables you to declare a remote cluster fault as a disaster, disconnect, or outage. Point to a table cell to view information about the VCS object.

**To access the Remote Cluster Status view**

1. From Cluster Explorer, click a cluster in the configuration tree.
2. In the view panel, click the **Remote Cluster Status** tab.
Accessing additional features of the Java Console

Use Cluster Manager to access the Template View, System Manager, User Manager, Command Center, Configuration Wizard, Notifier Resource Configuration Wizard, Remote Group Resource Configuration Wizard, Query Module, and Logs.

You can also use the Cluster Manager to run virtual fire drills (or HA fire drills) to check for any configurational discrepancies that might prevent a service group from coming online on a specific node.

Template view

The Template View displays the service group templates available in VCS. Templates are predefined service groups that define the resources, resource attributes, and dependencies within the service group. Use this view to add service groups to the cluster configuration, and copy the resources within a service group template to existing service groups.

In this window, the left pane displays the templates available on the system to which Cluster Manager is connected. The right pane displays the selected template's resource dependency graph.

Template files conform to the VCS configuration language and contain the extension .tf. These files reside in the VCS configuration directory.

To access the template view

From Cluster Explorer, click Templates on the Tools menu.
System Manager

Use System Manager to add and remove systems in a service group’s system list. A priority number (starting with 0) is assigned to indicate the order of systems on which the service group will start in case of a failover. If necessary, double-click the entry in the Priority column to enter a new value. Select the Startup check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.

To access system Manager

From Cluster Explorer, click the service group in the configuration tree, and click System Manager on the Tools menu.

or

In the Service Groups tab of the Cluster Explorer configuration tree, click a service group, and click Manage systems for a Service Group on the toolbar.
User Manager

User Manager enables you to add and delete user profiles and to change user privileges. If VCS is not running in secure mode, User Manager enables you to change user passwords. You must be logged in as Cluster Administrator to access User Manager.

To access user Manager
From Cluster Explorer, click User Manager on the File menu.
Command Center

Command Center enables you to build and execute VCS commands; most commands that are executed from the command line can also be executed through this window. The left pane of the window displays a **Commands** tree of all VCS operations. The right pane displays a view panel that describes the selected command. The bottom pane displays the commands being executed. The commands tree is organized into **Configuration** and **Operations** folders. Click the icon to the left of the **Configuration** or **Operations** folder to view its subfolders and command information in the right pane. Point to an entry in the commands tree to display information about the selected command.

To access Command Center

From Cluster Explorer, click **Command Center** on the **Tools** menu.

or

On the Cluster Explorer toolbar, click **Show Command Center**.
Configuration wizard

Use Configuration Wizard to create and assign service groups to systems in a cluster.

See “Creating service groups with the configuration wizard” on page 220.

To access Configuration Wizard
From Cluster Explorer, click Configuration Wizard on the Tools menu.

or
On the Cluster Explorer toolbar, click Launch Configuration Wizard.

Notifier Resource Configuration wizard

VCS provides a method for notifying an administrator of important events such as a resource or system fault. VCS includes a “notifier” component, which consists of the notifier daemon and the hanotify utility. This wizard enables you to configure the notifier component as a resource of type NotifierMngr as part of the ClusterService group.

See “Setting up VCS event notification using the Notifier wizard” on page 250.

To access Notifier Resource Configuration Wizard
From Cluster Explorer, click Notifier Wizard on the Tools menu.

or

Remote Group Resource Configuration Wizard

A RemoteGroup resource enables you to manage or monitor remote service groups.

See “Adding a RemoteGroup resource from the Java Console” on page 226.

To access Remote Group Resource Configuration Wizard
From Cluster Explorer, click Remote Group Resource Wizard... on the Tools menu.

or
Cluster query

Use Cluster Query to run SQL-like queries from Cluster Explorer. VCS objects that can be queried include service groups, systems, resources, and resource types. Some queries can be customized, including searching for the system’s online group count and specific resource attributes.

See "Querying the cluster configuration" on page 249.

To access the Query dialog box

From Cluster Explorer, click **Query** on the **Tools** menu.

or

In the Cluster Explorer toolbar, click **Query**.
Logs

The Logs dialog box displays the log messages generated by the VCS engine, VCS agents, and commands issued from Cluster Manager to the cluster. Use this dialog box to monitor and take actions on alerts on faulted global clusters and failed service group failover attempts.

**Note:** To ensure the time stamps for engine log messages are accurate, make sure to set the time zone of the system running the Java Console to the same time zone as the system running the VCS engine.

- Click the **VCS Logs** tab to view the log type, time, and details of an event. Each message presents an icon in the first column of the table to indicate the message type. Use this window to customize the display of messages by setting filter criteria.

- Click the **Agent Logs** tab to display logs according to system, resource type, and resource filter criteria. Use this tab to view the log type, time, and details of an agent event.

- Click the **Command Logs** tab to view the status (success or failure), time, command ID, and details of a command. The Command Log only displays commands issued in the current session.

- Click the **Alerts** tab to view situations that may require administrative action. Alerts are generated when a local group cannot fail over to any system in the local cluster, a global group cannot fail over, or a cluster fault takes place. A current alert will also appear as a pop-up window when you log on to a cluster through the console.
To access the Logs dialog box
From Cluster Explorer, click **Logs** on the **View** menu.

or

On the Cluster Explorer toolbar, click **Show the Logs**.

Server and user credentials

If VCS is running in secure mode, you can view server and user credentials used to connect to the cluster from Cluster Explorer.

**To view user credentials**
From Cluster Explorer, click **User Credentials** on the **View** menu.

**To view server credentials**
From Cluster Explorer, click **Server Credentials** on the **View** menu.
Administering Cluster Monitor

Use the Java Console to administer a cluster or simulated cluster by adding or reconfiguring a cluster panel in Cluster Monitor. To activate the connection of the procedures, log on to the cluster after completing the final step.

Configuring a new cluster panel

You must add a cluster panel for each cluster that you wish to connect to using the Java GUI.

To configure a new cluster panel

1. From Cluster Monitor, click **New Cluster** on the **File** menu. For simulated clusters, click **New Simulator** on the **File** menu.
   or
   Click **New Cluster** on the Cluster Monitor toolbar.

2. Enter the details to connect to the cluster:

   ![New Cluster - Connectivity Configuration](image)

   - Enter the host name or IP address of a system in the cluster.
   - If necessary, change the default port number of 14141; VCS Simulator uses a default port number of 14153. Note that you must use a different port to connect to each Simulator instance, even if these instances are running on the same system.
   - Enter the number of failover retries. VCS sets the default failover retries number to 12.
   - For simulated clusters, click the platform for the configuration.
   - Click **OK**. An inactive panel appears in Cluster Monitor.
Modifying a cluster panel configuration

Modify a cluster panel to point to another cluster, to change the port number, or the number of failover retries.

1. If Cluster Monitor is in the default expanded state, proceed to step 2. If Cluster Monitor is in the collapsed state:
   - On the View menu, click Expand.
   - or
   - On the View menu, click Stop when an active panel appears as the view panel.

2. Right-click the cluster panel. If the panel is inactive, proceed to step 4.

3. On the menu, click Logout. The cluster panel becomes inactive.

4. Right-click the inactive panel, and click Configure...

5. Edit the details to connect to the cluster:

   - Enter the host name or IP address of any system in the cluster.
   - Enter the port number and the number of failover retries. VCS sets the default port number to 14141 and failover retries number to 12; VCS Simulator uses a default port number of 14153.
   - For simulated panels, click the platform for the configuration.
   - Click OK.
Logging on to and off of a cluster

After you add or configure a cluster panel in Cluster Monitor, log on to a cluster to access Cluster Explorer. Use Cluster Monitor to log off a cluster when you have completed administering the cluster.

Logging on to a cluster

1. If Cluster Monitor is in the default expanded state, proceed to step 2. If Cluster Monitor is in the collapsed state:
   - On the View menu, click Expand.
   - or
   - On the View menu, click Stop when an active panel appears as the view panel.

2. Click the panel that represents the cluster you want to log on to.
   - or
   - If the appropriate panel is highlighted, click Login on the File menu.

3. Enter the information for the user:
   - **If the cluster is not running in secure mode:**
     - Enter the VCS user name and password.
     - Click OK.
   - **If the cluster is running in secure mode:**
     - Enter the credentials of a native user.
     - You can use nis or nis+ accounts or accounts set up on the local system.
     - If you do not enter the name of the domain, VCS assumes the domain is the local system.
     - If the user does not have root privileges on the system, VCS assigns guest privileges to the user. To override these privileges, add the domain user to the VCS administrators' list.
     - See “Administering user profiles” on page 197.
The Java Console connects to the cluster using the authentication broker and the domain type provided by the engine. To change the authentication broker or the domain type, click Advanced. See “About security services” on page 32.

Select a new broker and domain type, as required.

Click OK.

The Server Credentials dialog box displays the credentials of the cluster service to which the console is connected.

To disable this dialog box from being displayed every time you connect to the cluster, select the Do not show during startup check box.

Click OK to connect to the cluster.

The animated display shows various objects, such as service groups and resources, being transferred from the server to the console. Cluster Explorer is launched automatically upon initial logon, and the icons in the cluster panel change color to indicate an active panel.
Logging off of a cluster

1. If Cluster Monitor is in the default expanded state, proceed to step 2. If Cluster Monitor is in the collapsed state:
   - On the View menu, click **Expand**.
   - or
   - On the View menu, click **Stop** when an active panel appears as the view panel.

2. Right-click the active panel, and click **Logout**.
   - or
   - If the appropriate panel is highlighted, click **Logout** on the File menu.

Cluster Explorer closes and the Cluster Monitor panel becomes inactive. You may be prompted to save the configuration if any commands were executed on the cluster.

To log off from Cluster Explorer

Click **Log Out** on the File menu.
Administering user profiles

The Java Console enables a user with Cluster Administrator privileges to add, modify, and delete user profiles. The icon next to each user name in the User Manager dialog box indicates privileges for each user. Administrator and Operator privileges are separated into the cluster and group levels. See "About VCS user privileges and roles" on page 68.

Adding a user

1. From Cluster Explorer, click User Manager on the File menu.
2. In the User Manager dialog box, click New User.
3. In the Add User dialog box:
   - Enter the name of the user.
   - If the cluster is not running in secure mode, enter a password for the user and confirm it.
   - Select the appropriate check boxes to grant privileges to the user. To grant Group Administrator or Group Operator privileges, proceed to step the next step. Otherwise, proceed to the last step.
   - Click Select Groups...
   - Click the groups for which you want to grant privileges to the user and click the right arrow to move the groups to the Selected Groups box.
   - Click OK to exit the Select Group dialog box, then click OK again to exit the Add User dialog box.
4. Click Close.
Deleting a user

1. From Cluster Explorer, click **User Manager** on the **File** menu.
2. In the User Manager dialog box, click the user name.
3. Click **Remove User**.
4. Click **Yes**.
5. Click **Close**.

Changing a user password

A user with Administrator, Operator, or Guest privileges can change his or her own password. You must be logged on as Cluster Administrator to access User Manager. Before changing the password, make sure the configuration is in the read-write mode. Cluster administrators can change the configuration to the read-write mode.

**Note:** This module is not available if the cluster is running in secure mode.

To change a password as an administrator

1. From Cluster Explorer, click **User Manager** on the **File** menu.
2. Click the user name.
3. Click **Change Password**.
4. In the Change Password dialog box:
   - Enter the new password.
   - Re-enter the password in the **Confirm Password** field.
   - Click **OK**.
5. Click **Close**.

To change a password as an operator or guest

1. From Cluster Explorer, click **Change Password** on the **File** menu.
2. In the Change Password dialog box:
   - Enter the new password.
   - Reenter the password in the **Confirm Password** field.
   - Click **OK**.
3. Click **Close**.
Changing a user privilege

1. From Cluster Explorer, click User Manager on the File menu.
2. Click the user name.
3. Click Change Privileges and enter the details for user privileges:

   - Select the appropriate check boxes to grant privileges to the user. To grant Group Administrator or Group Operator privileges, proceed to the next step. Otherwise, proceed to the last step.
   - Click Select Groups.
   - Click the groups for which you want to grant privileges to the user, then click the right arrow to move the groups to the Selected Groups box.
   - Click OK in the Change Privileges dialog box, then click Close in the User Manager dialog box.
Assigning privileges for OS user groups for clusters running in secure mode

For clusters running in secure mode, you can assign privileges to native users at an operating system (OS) user group level. Assigning VCS privileges to an OS user group involves adding the user group in one (or more) of the following attributes:

- AdministratorGroups—for a cluster or for a service group.
- OperatorGroups—for a cluster or for a service group.

See “User privileges for OS user groups for clusters running in secure mode” on page 72.

To assign privileges to an OS user group

1. From Cluster Explorer configuration tree, select the cluster to assign privileges for the cluster or a service group to assign privileges for specific service groups.
2. From the view panel, click the Properties tab.
3. From the list of key attributes, click the edit icon against AdministratorGroups or OperatorGroups.
4. In the Edit Attribute dialog box:
   - Use the + button to add an element.
   - Click the newly added element and enter the name of the user group in the format group@domain.
   - Click OK.
Administering the cluster from Cluster Manager (Java console)

Administering service groups

Use the Java Console to administer service groups in the cluster. Use the console to add and delete, bring online and take offline, freeze and unfreeze, link and unlink, enable and disable, autoenable, switch, and flush service groups. You can also modify the system list for a service group.

Adding a service group

The Java Console provides several ways to add a service group to the systems in a cluster. Use Cluster Explorer, Command Center, or the Template View to perform this task.

To add a service group from Cluster Explorer

1. On the Edit menu, click Add, and click Service Group.
   or
   Click Add Service Group in the Cluster Explorer toolbar.
2. Enter the details of the service group:

   - Enter the name of the service group.
   - In the Available Systems box, click the systems on which the service group will be added.
   - Click the right arrow to move the selected systems to the Systems for Service Group box. The priority number (starting with 0) is automatically assigned to indicate the order of systems on which the service group will start in case of a failover. If necessary, double-click the entry in the Priority column to enter a new value.
   - Select the Startup check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.
Administering the cluster from Cluster Manager (Java console)

Administering service groups

- Click the appropriate service group type. A failover service group runs on only one system at a time; a parallel service group runs concurrently on multiple systems.

- To add a new service group based on a template, click Templates... Otherwise, proceed to step 2g. (Alternative method to add a new service group based on a template: From Cluster Explorer, click Templates on the Tools menu. Right-click the Template View panel, and click Add as Service Group from the menu.)

- Click the appropriate template name, then click OK.

- Click Show Command in the bottom left corner if you want to view the command associated with the service group. Click Hide Command to close the view of the command.

- Click OK.

To add a service group from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Cluster Objects > Add Service Group.

   or

   Click Add service group in the Command Center toolbar.

2. Enter the name of the service group.

3. In the Available Systems box, click the systems on which the service group will be added.

4. Click the right arrow to move the selected systems to the Systems for Service Group box. The priority number (starting with 0) is automatically assigned to indicate the order of systems on which the service group will start in case of a failover. If necessary, double-click the entry in the Priority column to enter a new value.
Select the **Startup** check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.

5. Click the appropriate service group type. A failover service group runs on only one system at a time; a parallel service group runs concurrently on multiple systems.

6. To add a new service group based on a template, click **Templates...** Otherwise, proceed to step 9.

7. Click the appropriate template name.

8. Click **OK**.

9. Click **Apply**.
To add a service group from the template view

1. From Cluster Explorer, click **Templates...** on the **Tools** menu.

2. Right-click the Template View panel, and click **Add as Service Group** from the pop-up menu. This adds the service group template to the cluster configuration file without associating it to a particular system.

3. Use System Manager to add the service group to systems in the cluster. See “**System Manager**” on page 185.
Deleting a service group

Delete a service group from Cluster Explorer or Command Center.

Note: You cannot delete service groups with dependencies. To delete a linked service group, you must first delete the link.

To delete a service group from Cluster Explorer

1. In the Service Groups tab of the configuration tree, right-click the service group.
   or
   Click a cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.

2. Click Delete from the menu.

3. Click Yes.

To delete a service group from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Cluster Objects > Delete Service Group.

2. Click the service group.

3. Click Apply.
Bringing a service group online

To bring a service group online from the Cluster Explorer configuration tree
1. In the Service Groups tab of the configuration tree, right-click the service group.

   or

   Click a cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.

2. Click Online, and click the appropriate system from the menu. Click Any System if you do not need to specify a system.

To bring a service group online from the Cluster Explorer toolbar
1. Click Online Service Group on the Cluster Explorer toolbar.

2. Specify the details for the service group:

   ■ Click the service group.
   ■ For global groups, select the cluster in which to bring the group online.
   ■ Click the system on which to bring the group online, or select the Any System check box.
   ■ Select the No Preonline check box to bring the service group online without invoking the preonline trigger.
   ■ Click Show Command in the bottom left corner to view the command associated with the service group. Click Hide Command to close the view of the command.
   ■ Click OK.
To bring a service group online from Command Center

1. In the Command Center configuration tree, expand **Commands > Operations > Controls > Online Service Group**.
   
or
   Click **Bring service group online** in the Command Center toolbar.

2. Click the service group.

3. For global groups, select the cluster in which to bring the group online.

4. Click the system on which to bring the group online, or select the **Any System** check box.

5. Click **Apply**.
Taking a service group offline

To take a service group offline from Cluster Explorer configuration tree

1. In the **Service Groups** tab of the configuration tree, right-click the service group.
   
or
   Click a cluster in the configuration tree, click the **Service Groups** tab, and right-click the service group icon in the view panel.

2. Click **Offline**, and click the appropriate system from the menu. Click **All Systems** to take the group offline on all systems.

To take a service group offline from the Cluster Explorer toolbar

1. Click **Offline Service Group** in the Cluster Explorer toolbar.

2. Enter the details of the service group:

   ■ Click the service group.
   ■ For global groups, select the cluster in which to take the group offline.
   ■ Click the system on which to take the group offline, or click **All Systems**.
   ■ Click **Show Command** in the bottom left corner if you want to view the command associated with the service group. Click **Hide Command** to close the view of the command.
   ■ Click **OK**.
To take a service group offline from Command Center

1. In the Command Center configuration tree, expand **Commands > Operations > Controls > Offline Service Group**.
   
   or
   
   Click **Take service group offline** in the Command Center toolbar.

2. Click the service group.

3. For global groups, select the cluster in which to take the group offline.

4. Click the system on which to take the group offline, or click the **All Systems** check box.

5. Click **Apply**.

Switching a service group

The process of switching a service group involves taking it offline on its current system and bringing it online on another system.

To switch a service group from Cluster Explorer

1. In the **Service Groups** tab of the configuration tree, right-click the service group.

   or

   Click the cluster in the configuration tree, click the **Service Groups** tab, and right-click the service group icon in the view panel.

2. Click **Switch To**, and click the appropriate system from the menu.

To switch a service group from Command Center

1. In the Command Center configuration tree, expand **Commands > Operations > Controls > Switch Service Group**.

2. Click the service group.

3. For global groups, select the cluster in which to switch the service group.

4. Click the system on which to bring the group online, or select the **Any System** check box.

5. Click **Apply**.
Freezing a service group

Freeze a service group to prevent it from failing over to another system. The freezing process stops all online and offline procedures on the service group. Note that you cannot freeze a service group when the service group state is in transition.

**To freeze a service group from Cluster Explorer**

1. In the **Service Groups** tab of the configuration tree, right-click the service group.
   
   or
   
   Click the cluster in the configuration tree, click the **Service Groups** tab, and right-click the service group icon in the view panel.

2. Click **Freeze**, and click **Temporary** or **Persistent** from the menu. The persistent option maintains the frozen state after a reboot if you save this change to the configuration.

**To freeze a service group from Command Center**

1. In the Command Center configuration tree, expand **Commands > Operations > Availability > Freeze Service Group**.

2. Click the service group.

3. Select the **persistent** check box if necessary. The persistent option maintains the frozen state after a reboot if you save this change to the configuration.

4. Click **Apply**.
Unfreezing a service group

Unfreeze a frozen service group to perform online or offline operations on the service group.

To unfreeze a service group from Cluster Explorer
1  In the Service Groups tab of the configuration tree, right-click the service group.
   or
   Click the cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.
2  Click Unfreeze.

To unfreeze a service group from Command Center
1  In the Command Center configuration tree, expand Commands > Operations > Availability > Unfreeze Service Group.
2  Click the service group.
3  Click Apply.
Enabling a service group

Enable a service group before bringing it online. A service group that was manually disabled during a maintenance procedure on a system may need to be brought online after the procedure is completed.

To enable a service group from Cluster Explorer

1. In the Service Groups tab of the configuration tree, right-click the service group.
   
or
   Click the cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.

2. Click Enable, and click the appropriate system from the menu. Click All Systems to enable the group on all systems.

To enable a service group from Command Center

1. In the Command Center configuration tree, expand Commands > Operations > Availability > Enable Service Group.

2. Click the service group.

3. Select the Per System check box to enable the group on a specific system instead of all systems.

4. Click Apply.
Disabling a service group

Disable a service group to prevent it from coming online. This process temporarily stops VCS from monitoring a service group on a system undergoing maintenance operations.

To disable a service group from Cluster Explorer

1 In the Service Groups tab of the configuration tree, right-click the service group.
   or
   Click the cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.

2 Click Disable, and click the appropriate system in the menu. Click All Systems to disable the group on all systems.

To disable a service group from Command Center

1 In the Command Center configuration tree, expand Commands > Operations > Availability > Disable Service Group.

2 Click the service group.

3 Select the Per System check box to disable the group on a specific system instead of all systems.

4 Click Apply.
Autoenabling a service group

A service group is autodisabled until VCS probes all resources and checks that they are ready to come online. Autoenable a service group in situations where the VCS engine is not running on one of the systems in the cluster, and you must override the disabled state of the service group to enable the group on another system in the cluster.

To autoenable a service group from Cluster Explorer
1. In the Service Groups tab of the configuration tree, right-click the service group.
   or
   Click the cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.
2. Click Autoenable, and click the appropriate system from the menu.

To autoenable a service group from Command Center
1. In the Command Center configuration tree, expand Commands > Operations > Availability > Autoenable Service Group.
2. Click the service group.
3. Click the system on which to autoenable the group.
4. Click Apply.
Flushing a service group

As a service group is brought online or taken offline, the resources within the group are brought online and taken offline. If the online or offline operation hangs on a particular resource, flush the service group to halt the operation on the resources waiting to go online or offline. Flushing a service group typically leaves the cluster in a partial state. After completing this process, resolve the issue with the particular resource (if necessary) and proceed with starting or stopping the service group.

To flush a service group from Cluster Explorer
1  In the Service Groups tab of the configuration tree, right-click the service group.
   or
   Click the cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.
2  Click Flush, and click the appropriate system from the menu.

To flush a service group from Command Center
1  In the Command Center configuration tree, expand Commands > Operations > Availability > Flush Service Group.
2  Click the service group.
3  Click the system on which to flush the service group.
4  Click Apply.
Linking service groups

To link a service group from Cluster Explorer

1. Click a cluster in the configuration tree.

2. In the view panel, click the **Service Groups** tab. This opens the service group dependency graph. To link a parent group with a child group:
   - Click **Link**.
   - Click the parent group.
   - Move the mouse toward the child group. The yellow line “snaps” to the child group. If necessary, press Esc on the keyboard to delete the line between the parent and the pointer before it snaps to the child.
   - Click the child group.
   - In the Link Service Groups dialog box, click the group relationship and dependency type.
     See “About service group dependencies” on page 518.

   - Click **OK**.
You can also link the service groups by performing steps 1 and 2, right-clicking the parent group, and clicking Link from the menu. In the dialog box, click the child group, relationship, dependency type, and click OK.

To link a service group from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Dependencies > Link Service Groups.
2. Click the parent resource group in the Service Groups box. After selecting the parent group, the potential groups that can serve as child groups are displayed in the Child Service Groups box.
3. Click a child service group.
4. Click the group relationship and dependency type. See “About service group dependencies” on page 518.
5. Click Apply.
Unlinking service groups

To delete a service group dependency from Cluster Explorer
1. Click a cluster in the configuration tree.
2. In the view panel, click the **Service Groups** tab.
3. In the Service Group view, right-click the link between the service groups.
4. Click **Unlink** from the menu.
5. Click **Yes**.

To delete a service group dependency from Command Center
1. In the Command Center configuration tree, expand **Commands > Configuration > Dependencies > Unlink Service Groups**.
2. Click the parent resource group in the **Service Groups** box. After selecting the parent group, the corresponding child groups are displayed in the **Child Service Groups** box.
3. Click the child service group.
4. Click **Apply**.
Managing systems for a service group

From Cluster Explorer, use System Manager to add and remove systems in a service group’s system list.

**To add a system to the service group’s system list**

1. In the System Manager dialog box, click the system in the Available Systems box.
2. Click the right arrow to move the available system to the Systems for Service Group table.
3. Select the Startup check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.
4. The priority number (starting with 0) is assigned to indicate the order of systems on which the service group will start in case of a failover. If necessary, double-click the entry in the Priority column to enter a new value.
5. Click OK.

**To remove a system from the service group’s system list**

1. In the System Manager dialog box, click the system in the Systems for Service Group table.
2. Click the left arrow to move the system to the Available Systems box.
3. Click OK.
Creating service groups with the configuration wizard

This section describes how to create service groups using the configuration wizard.

To create a service group using the configuration wizard

1. Open the Configuration Wizard. From Cluster Explorer, click Configuration Wizard on the Tools menu.

2. Read the information on the Welcome dialog box and click Next.

3. Specify the name and target systems for the service group:
   - Enter the name of the group.
   - Click the target systems in the Available Systems box.
   - Click the right arrow to move the systems to the Systems for Service Group table. To remove a system from the table, click the system and click the left arrow.
   - Select the Startup check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.
   - The priority number (starting with 0) is automatically assigned to indicate the order of systems on which the service group will start in case of a failover. If necessary, double-click the entry in the Priority column to enter a new value.
   - Click the service group type.
   - Click Next.

4. Click Next again to configure the service group with a template and proceed to step 7. Click Finish to add an empty service group to the selected cluster systems and configure it at a later time.
5 Click the template on which to base the new service group. The Templates box lists the templates available on the system to which Cluster Manager is connected. The resource dependency graph of the templates, the number of resources, and the resource types are also displayed. Click Next.

6 If a window notifies you that the name of the service group or resource within the service group is already in use, proceed to step 9. Otherwise, proceed to step 10.

7 Click Next to apply all of the new names listed in the table to resolve the name clash.
   or
   Modify the clashing names by entering text in the field next to the Apply button, clicking the location of the text for each name from the Correction drop-down list box, clicking Apply, and clicking Next.

8 Click Next to create the service group. A progress indicator displays the status.

9 After the service group is successfully created, click Next to edit attributes using the wizard. Click Finish to edit attributes at a later time using Cluster Explorer.

10 Review the attributes associated with the resources of the service group. If necessary, proceed to step 11 to modify the default values of the attributes. Otherwise, proceed to step 12 to accept the default values and complete the configuration.

11 Modify the values of the attributes (if necessary).
   - Click the resource.
   - Click the attribute to be modified.
   - Click the Edit icon at the end of the table row.
   - In the Edit Attribute dialog box, enter the attribute values.
   - Click OK.
Repeat the procedure for each resource and attribute.

12 Click Finish.
Administering resources

Use the Java Console to administer resources in the cluster. Use the console to add and delete, bring online and take offline, probe, enable and disable, clear, and link and unlink resources. You can also import resource types to the configuration.

Adding a resource

The Java Console provides several ways to add a resource to a service group. Use Cluster Explorer or Command Center to perform this task.

To add a resource from Cluster Explorer

1  In the Service Groups tab of the Cluster Explorer configuration tree, click a service group to which the resource will be added.
2  On the Edit menu, click Add, and click Resource.
   or
   Click Add Resource in the Cluster Explorer toolbar.
3  Enter the details of the resource:
   ■  Enter the name of the resource.
   ■  Click the resource type.
   ■  Edit resource attributes according to your configuration. The Java Console also enables you to edit attributes after adding the resource.
   ■  Select the Critical and Enabled check boxes, if applicable. The Critical option is selected by default.
   A critical resource indicates the service group is faulted when the resource, or any resource it depends on, faults. An enabled resource indicates agents monitor the resource; you must specify the values of mandatory attributes before enabling a resource. If a resource is
created dynamically while VCS is running, you must enable the resource before VCS monitors it. VCS will not bring a disabled resource nor its children online, even if the children are enabled.

- Click Show Command in the bottom left corner to view the command associated with the resource. Click Hide Command to close the view of the command.
- Click OK.

To add a resource from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Cluster Objects > Add Resource.

   or

2. Click Add resource in the Command Center toolbar.

3. Enter the name of the resource.
4. Click the resource type.
5. Edit resource attributes according to your configuration. The Java Console also enables you to edit attributes after adding the resource.
6. Select the Critical and Enabled check boxes, if applicable. The Critical option is selected by default.

   A critical resource indicates the service group is faulted when the resource, or any resource it depends on, faults. An enabled resource indicates agents monitor the resource; you must specify the values of mandatory attributes
before enabling a resource. If a resource is created dynamically while VCS is running, you must enable the resource before VCS monitors it. VCS will not bring a disabled resource nor its children online, even if the children are enabled.

To add a resource from the Template view

1. From Cluster Explorer, click **Templates...** on the **Tools** menu.
2. In the left pane of the Template View, click the template from which to add resources to your configuration.
3. In the resource graph, right-click the resource to be added to your configuration.
4. Click **Copy**, and click **Self** from the menu to copy the resource. Click **Copy**, and click **Self and Child Nodes** from the menu to copy the resource with its dependent resources.
5. In the **Service Groups** tab of the Cluster Explorer configuration tree, click the service group to which to add the resources.
6. In the Cluster Explorer view panel, click the **Resources** tab.
7. Right-click the Resource view panel and click **Paste** from the menu. After the resources are added to the service group, edit the attributes to configure the resources.
Adding a RemoteGroup resource from the Java Console

A RemoteGroup resource is typically useful in scenarios where resources configured in a local service group are dependant on the state of a remote failover service group. For example, a web-server application running in a local cluster could be dependant on a database application running in a remote cluster.

Note that the RemoteGroup agent represents that state of a failover service group; the agent is not supported with parallel service groups.

A RemoteGroup resource monitors the state of a remote service group in a local cluster. Once you have added the RemoteGroup resource to a local service group, you can link the resource to the existing resources of the service group. You must have administrative privileges to configure RemoteGroup resources.

To add a RemoteGroup resource

1. On the Tools menu, click Add Remote Group Resource...
   or
   Click Configure Remote Group Resource Wizard in the Cluster Explorer toolbar.

2. Read the information on the Welcome dialog box and click Next.

3. In the Remote Group Resource Name dialog box, specify the name of the resource and the service group to which the resource will be added. Click Next.

4. In the Remote Cluster Information dialog box:
   ■ Specify the name or IP address of a node in the remote cluster.
   ■ Specify the port on the remote node on which the resource will communicate.
   ■ Specify a username for the remote cluster.
   ■ Specify a password for the user.
   ■ Select the check box if you wish to specify advance options to connect to a cluster running in secure mode. Otherwise, proceed to the last step.
     ■ Specify the domain of which the node is a part.
     ■ Select a domain type.
     ■ Specify the authentication broker and port.
   ■ Click Next.
In the Remote Group Resource Details dialog box:

- Select a group you wish to monitor.
- Select the mode of monitoring.
  - Choose the **MonitorOnly** option to monitor the remote service group. You will not be able to perform online or offline operations on the remote group.
  - Choose the **OnlineOnly** option to monitor the remote service group and bring the remote group online from the local cluster.
  - Choose the **OnOff** option to monitor the remote service group, bring the remote group online, and take it offline from the local cluster.
- Specify whether the RemoteGroup resource should monitor the state of the remote group on a specific system or any system in the remote cluster.
  - Choose the **Any System** option to enable the RemoteGroup resource to monitor the state of the remote service group irrespective of the system on which it is online.
  - Choose the **Specific System** option to enable the RemoteGroup resource to monitor the state of the remote group on a specific system in the remote cluster. Both service groups must be configured on the same number of systems. This option provides one-to-one mapping between the local and remote systems. The **Local Systems** list displays the systems on which the RemoteGroup resource is configured. Click the fields under the **Remote Systems** list and select the systems from drop-down list. If the remote group fails over to another system in
the remote cluster, the RemoteGroup resource will also fail over to
the corresponding system in the local cluster.

- Click Next.

6 Review the text in the dialog box and click Finish to add the RemoteGroup
resource to the specified service group in the local cluster. You must now
create dependencies between the RemoteGroup resource and the existing
resources of the service group.
See “Linking resources” on page 236.

Deleting a resource

To delete a resource from Cluster Explorer

1 In the Service Groups tab of the configuration tree, right-click the resource.
   or
   Click a service group in the configuration tree, click the Resources tab, and
   right-click the resource icon in the view panel.

2 Click Delete from the menu.

3 Click Yes.

To delete a resource from Command Center

1 In the Command Center configuration tree, expand Commands >
   Configuration > Cluster Objects > Delete Resource.

2 Click the resource.

3 Click Apply.

Bringing a resource online

To bring a resource online from Cluster Explorer

1 In the Service Groups tab of the configuration tree, right-click the resource.
   or
   Click a service group in the configuration tree, click the Resources tab, and
   right-click the resource icon in the view panel.

2 Click Online, and click the appropriate system from the menu.

To bring a resource online from Command Center

1 In the Command Center configuration tree, expand Commands > Operations
   > Controls > Online Resource.

2 Click a resource.
3  Click a system on which to bring the resource online.
4  Click Apply.

Taking a resource offline

To take a resource offline from Cluster Explorer
1  In the Service Groups tab of the configuration tree, right-click the resource.
   or
   Click a service group in the configuration tree, click the Resources tab, and
   right-click the resource icon in the view panel.
2  Click Offline, and click the appropriate system from the menu.

To take a resource offline from Command Center
1  In the Command Center configuration tree, expand Commands > Operations
   > Controls > Offline Resource.
2  Click a resource.
3  Click a system on which to take the resource offline.
4  If necessary, select the ignoreparent check box to take a selected child
   resource offline, regardless of the state of the parent resource. This option is
   only available through Command Center.
5  Click Apply.
Taking a resource offline and propagating the command

Use the Offline Propagate (OffProp) feature to propagate the offline state of a parent resource. This command signals that resources dependent on the parent resource should also be taken offline.

Use the Offline Propagate (OffProp) “ignoreparent” feature to take a selected resource offline, regardless of the state of the parent resource. This command propagates the offline state of the selected resource to the child resources. The “ignoreparent” option is only available in Command Center.

To take a resource and its child resources offline from Cluster Explorer

1. In the Resources tab of the configuration tree, right-click the resource.
2. Click Offline Prop, and click the appropriate system from the menu.

To take a resource and its child resources offline from Command Center

1. In the Command Center configuration tree, expand Commands > Operations > Controls > OffProp Resource.
2. Click the resource.
3. Click the system on which to take the resource, and the child resources, offline.
4. Click Apply.

To take child resources offline from Command Center while ignoring the state of the parent resource

1. In the Command Center configuration tree, expand Commands > Operations > Controls > OffProp Resource.
2. Click the resource.
3. Click the system on which to take the resource, and the child resources, offline.
4. Select the ignoreparent check box.
5. Click Apply.
Probing a resource

Probe a resource to check that it is configured and ready to bring online.

To probe a resource from Cluster Explorer
1  In the Service Groups tab of the configuration tree, right-click the resource.
2  Click Probe, and click the appropriate system from the menu.

To probe a resource from Command Center
1  In the Command Center configuration tree, expand Commands > Operations > Controls > Probe Resource.
2  Click the resource.
3  Click the system on which to probe the resource.
4  Click Apply.
Overriding resource type static attributes

You can override some resource type static attributes and assign them resource-specific values. When a static attribute is overridden and the configuration is saved, the main.cf file includes a line in the resource definition for the static attribute and its overridden value.

To override resource type static attribute

1. Right-click the resource in the Service Groups tab of the configuration tree or in the Resources tab of the view panel.
2. Click Override Attributes.
3. Select the attributes to override.
4. Click OK.
   The selected attributes appear in the Overridden Attributes table in the Properties view for the resource.
5. To modify the default value of an overridden attribute, click the icon in the Edit column of the attribute.

To restore default settings to a type's static attribute

1. Right-click the resource in the Service Groups tab of the configuration tree or in the Resources tab of the view panel.
2. Click Remove Attribute Overrides.
3. Select the overridden attributes to be restored to their default settings.
4. Click OK.
Enabling resources in a service group

Enable resources in a service group to bring the disabled resources online. A resource may have been manually disabled to temporarily stop VCS from monitoring the resource. You must specify the values of mandatory attributes before enabling a resource.

To enable an individual resource in a service group

1. From Cluster Explorer, click the Service Groups tab of the configuration tree.
2. Right-click a disabled resource in the configuration tree, and click Enabled from the menu.

To enable all resources in a service group from Cluster Explorer

1. From Cluster Explorer, click the Service Groups tab in the configuration tree.
2. Right-click the service group.
3. Click Enable Resources.

To enable all resources in a service group from Command Center

1. In the Command Center configuration tree, expand Commands > Operations > Availability > Enable Resources for Service Group.
2. Click the service group.
3. Click Apply.
Disabling resources in a service group

Disable resources in a service group to prevent them from coming online. This disabling process is useful when you want VCS to temporarily “ignore” resources (rather than delete them) while the service group is still online.

To disable an individual resource in a service group
1. From Cluster Explorer, click the Service Groups tab in the Cluster Explorer configuration tree.
2. Right-click a resource in the configuration tree. An enabled resource will display a check mark next to the Enabled option that appears in the menu.
3. Click Enabled from the menu to clear this option.

To disable all resources in a service group from Cluster Explorer
1. From Cluster Explorer, click the Service Groups tab in the configuration tree.
2. Right-click the service group and click Disable Resources.

To disable all resources in a service group from Command Center
1. In the Command Center configuration tree, expand Commands > Operations > Availability > Disable Resources for Service Group.
2. Click the service group.
3. Click Apply.
Clearing a resource

Clear a resource to remove a fault and make the resource available to go online. A resource fault can occur in a variety of situations, such as a power failure or a faulty configuration.

To clear a resource from Cluster Explorer

1. In the Service Groups tab of the configuration tree, right-click the resource.
2. Click Clear Fault, and click the system from the menu. Click Auto instead of a specific system to clear the fault on all systems where the fault occurred.

To clear a resource from Command Center

1. In the Command Center configuration tree, expand Commands > Operations > Availability > Clear Resource.
2. Click the resource. To clear the fault on all systems listed in the Systems box, proceed to step 5. To clear the fault on a specific system, proceed to step 3.
3. Select the Per System check box.
4. Click the system on which to clear the resource.
5. Click Apply.
Linking resources

Use Cluster Explorer or Command Center to link resources in a service group.

To link resources from Cluster Explorer

1. In the configuration tree, click the **Service Groups** tab.
2. Click the service group to which the resources belong.
3. In the view panel, click the **Resources** tab. This opens the resource dependency graph. To link a parent resource with a child resource:
   - Click **Link...**
   - Click the parent resource.
   - Move the mouse towards the child resource. The yellow line “snaps” to the child resource. If necessary, press Esc to delete the line between the parent and the pointer before it snaps to the child.
   - Click the child resource.
   - In the Confirmation dialog box, click **Yes**.
   - or
   - Right-click the parent resource, and click **Link** from the menu. In the Link Resources dialog box, click the resource that will serve as the child. Click **OK**.

![Link Resources dialog box](image)

- Click **OK**.

To link resources from Command Center

1. In the Command Center configuration tree, expand **Commands > Configuration > Dependencies > Link Resources**.
2. Click the service group to contain the linked resources.
3 Click the parent resource in the **Service Group Resources** box. After selecting the parent resource, the potential resources that can serve as child resources are displayed in the **Child Resources** box.

4 Click a child resource.

5 Click **Apply**.
Unlinking resources

Use Cluster Explorer or Command Center to unlink resources in a service group.

To unlink resources from Cluster Explorer
1. From the configuration tree, click the **Service Groups** tab.
2. Click the service group to which the resources belong.
3. In the view panel, click the **Resources** tab.
4. In the Resources View, right-click the link between the resources.
5. Click **Unlink...** from the menu.

6. In the Question dialog box, click **Yes** to delete the link.
To unlink resources from Command Center

1. In the Command Center configuration tree, expand **Commands > Configuration > Dependencies > Unlink Resources**.
2. Click the service group that contains the linked resources.
3. Click the parent resource in the **Service Group Resources** box. After selecting the parent resource, the corresponding child resources are displayed in the **Child Resources** box.
4. Click the child resource.
5. Click **Apply**.
Invoking a resource action

Cluster Explorer enables you to initiate a predefined action script. Some examples of predefined resource actions are splitting and joining disk groups.

To invoke a resource action
1. In the Service Groups tab of the configuration tree, right-click the resource.
2. Click Actions...
3. Specify the details of the action:
   - Click the predefined action to execute.
   - Click the system on which to execute the action.
   - To add an argument, click the Add icon (+) and enter the argument. Click the Delete icon (-) to remove an argument.
   - Click OK.
Refreshing the ResourceInfo attribute

Refresh the ResourceInfo attribute to view the latest values for that attribute.

To refresh the ResourceInfo attribute
1. In the Service Groups tab of the configuration tree, right-click the resource.
2. Click Refresh ResourceInfo, and click the system on which to refresh the attribute value.

Clearing the ResourceInfo attribute

Clear the ResourceInfo attribute to reset all the parameters in this attribute.

To clear the parameters of the ResourceInfo attribute
1. In the Service Groups tab of the configuration tree, right-click the resource.
2. Click Clear ResourceInfo, and click the system on which to reset the attribute value.

Importing resource types

The Java Console enables you to import resource types into your configuration (main.cf). For example, use this procedure to import the types.cf for enterprise agents to your configuration. You cannot import resource types that already exist in your configuration.

To import a resource type from Cluster Explorer
1. On the File menu, click Import Types.
2. In the Import Types dialog box:
   - Click the file from which to import the resource type. The dialog box displays the files on the system that Cluster Manager is connected to.
   - Click Import.

Running HA fire drill from the Java Console

Use the Cluster Manager to run HA fire drills for specific resources in a local cluster. You can run HA fire drill for agents that support the functionality.

To run HA fire drill
1. On the Cluster Explorer toolbar, click Virtual Fire Drill.
   or
2. From Cluster Explorer, click Virtual Fire Drill... on the Tools menu.
2 Specify details to run a virtual fire drill.

- Select the type of check to run.
- Select a service group for which to run the infrastructure checks. Make sure you select a service group that is online.
- Select a system to run the checks on.
- Click **Perform checks**.
- View the result of the check. If the virtual fire drill reports any errors, right-click the resource and select **Fix it**.

3 Click **Close**.
Administering systems

Use the Java Console to administer systems in the cluster. Use the console to add, delete, freeze, and unfreeze systems.

Adding a system

Cluster Explorer and Command Center enable you to add a system to the cluster. A system must have an entry in the LLTTab configuration file before it can be added to the cluster.

To add a system from Cluster Explorer

1. On the Edit menu, click Add, and click System.
   or
   Click Add System on the Cluster Explorer toolbar.
2. Enter the name of the system.
3. Click Show Command in the bottom left corner to view the command associated with the system. Click Hide Command to close the view of the command.
4. Click OK.

To add a system from Command Center

1. Click Add System in the Command Center toolbar.
   or
   In the Command Center configuration tree, expand Commands > Configuration > Cluster Objects > Add System.
2. Enter the name of the system.
3. Click Apply.

Deleting a system

To delete a system from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Cluster Objects > Delete System.
2. Click the system.
3. Click Apply.
Freezing a system

Freeze a system to prevent service groups from coming online on the system.

**To freeze a system from Cluster Explorer**
1. Click the **Systems** tab of the configuration tree.
2. In the configuration tree, right-click the system, click **Freeze**, and click **Temporary** or **Persistent** from the menu. The persistent option maintains the frozen state after a reboot if the user saves this change to the configuration.

**To freeze a system from Command Center**
1. In the Command Center configuration tree, expand **Commands** > **Operations** > **Availability** > **Freeze System**.
2. Click the system.
3. If necessary, select the **persistent** and **evacuate** check boxes. The evacuate option moves all service groups to a different system before the freeze operation takes place. The persistent option maintains the frozen state after a reboot if the user saves this change to the configuration.
4. Click **Apply**.

Unfreezing a system

Unfreeze a frozen system to enable service groups to come online on the system.

**To unfreeze a system from Cluster Explorer**
1. Click the **Systems** tab of the configuration tree.
2. In the configuration tree, right-click the system and click **Unfreeze**.

**To unfreeze a system from Command Center**
1. In the Command Center configuration tree, expand **Commands** > **Operations** > **Availability** > **Unfreeze System**.
2. Click the system.
3. Click **Apply**.
Administering clusters

Use the Java Console to specify the clusters you want to view from the console, and to modify the VCS configuration. The configuration details the parameters of the entire cluster. Use Cluster Explorer or Command Center to open, save, and “save and close” a configuration. VCS Simulator enables you to administer the configuration on the local system while VCS is offline.

Opening a cluster configuration

Use Cluster Explorer or Command Center to open or make changes to the VCS configuration.

To open a configuration from Cluster Explorer
On the File menu, click Open Configuration.

or

Click Open Configuration on the Cluster Explorer toolbar.

To open a configuration from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Configuration File > Open Configuration.

2. Click Apply.

Saving a cluster configuration

After updating the VCS configuration, use Cluster Explorer or Command Center to save the latest configuration to disk while maintaining the configuration state in read-write mode.

To save a configuration from Cluster Explorer
On the File menu, click Save Configuration.

or

Click Save Configuration on the Cluster Explorer toolbar.

To save a configuration from Command Center

1. In the Command Center configuration tree, expand Commands > Configuration > Configuration File > Save Configuration.

2. Click Apply.
Saving and closing a cluster configuration

After updating the VCS configuration, use Cluster Explorer or Command Center to save the latest configuration to disk, and close or change the configuration state to read-only mode.

To save and close a configuration from Cluster Explorer
On the File menu, click Close Configuration.

or

Click Save and Close Configuration on the Cluster Explorer toolbar.

To save and close a configuration from Command Center

1 In the Command Center configuration tree, expand Commands > Configuration > Configuration File > Close Configuration.

2 Click Apply.

Executing commands

Use Command Center to execute commands on a cluster. Command Center enables you to run commands organized as “Configuration” and “Operation.”

To execute a command from Command Center

1 From Command Center, click the command from the command tree. If necessary, expand the tree to view the command.

2 In the corresponding command interface, click the VCS objects and appropriate options (if necessary).

3 Click Apply.
Editing attributes

Use the Java Console to edit attributes of VCS objects. By default, the Java Console displays key attributes and type specific attributes. To view all attributes associated with an object, click **Show all attributes**.

**To edit an attribute from Cluster Explorer**

1. From the Cluster Explorer configuration tree, click the object whose attributes you want to edit.

2. In the view panel, click the **Properties** tab. If the attribute does not appear in the Properties View, click **Show all attributes**. This opens the Attributes View.

3. In the Properties or Attributes View, click the icon in the **Edit** column of the **Key Attributes** or **Type Specific Attributes** table. In the Attributes View, click the icon in the **Edit** column of the attribute.

4. In the Edit Attribute dialog box, enter the changes to the attribute values.
   - **To edit a scalar value:**
     Enter or click the value.
   - **To edit a non-scalar value:**
     Use the + button to add an element. Use the - button to delete an element.
   - **To change the attribute’s scope:**
     Click the **Global** or **Per System** option.
   - **To change the system for a local attribute:**
     Click the system from the menu.

5. Click **OK**.

**To edit an attribute from Command Center**

1. In the Command Center configuration tree, expand **Commands > Configuration > Attributes > Modify vcs_object Attributes**.

2. Click the VCS object from the menu.
3 In the attribute table, click the icon in the Edit column of the attribute.

4 In the Edit Attribute dialog box, enter the changes to the attribute values.

   To edit a scalar value:
   Enter or click the value.

   To edit a non-scalar value:
   Use the + button to add an element. Use the - button to delete an element.

   To change the attribute’s scope:
   Click the Global or Per System option.

   To change the system for a local attribute:
   Click the system from the menu.

5 Click OK.
Querying the cluster configuration

1. From Cluster Explorer, click **Query** on the **Tools** menu.
   
   or
   
   On the Cluster Explorer toolbar, click **Query**.

2. Enter the details of the query:

   - Click the VCS object to search.
   - Depending on the selected object, click the specific entity to search.
   - Click the appropriate phrase or symbol between the search item and value.
   - Click the appropriate value for the specified query. Certain queries allow the user to enter specific filter information:
     - Click **System**, click **Online Group Count**, click `<`, and type the required value in the blank field.
     - or
     - Click **Resource**, click [provide attribute name] and type in the name of an attribute, click `=` or `contains`, and type the appropriate value of the attribute in the blank field. For example, click **Resource**, click [provide attribute name] and type in `c:\temp` in the blank field.
   - To use additional queries, click `+` as many times as necessary to select the appropriate options. Click `-` to reduce the number of queries.
   - Click **AND** or **OR** for each filter selection.
   - Click **Search**. The results appear in tabular format at the bottom of the dialog box. To search a new item, click **Reset** to reset the dialog box to its original blank state.
Setting up VCS event notification using the Notifier wizard

The information presented here assumes that you need to create both the ClusterService group and the Notifier resource. If the ClusterService group exists but the Notifier resource is configured under another group, you can modify the attributes of the existing Notifier resource and system list for that group. If the ClusterService group is configured but the Notifier resource is not configured, the Notifier resource will be created and added to the ClusterService group.

To set up event notification using the Notifier wizard

1. From Cluster Explorer, click **Notifier Wizard...** on the **Tools** menu.
   or
   On the Cluster Explorer toolbar, click **Launch Notifier Resource Configuration Wizard**.

2. Click **Next**.

3. In the dialog box:

   - Enter the name of the resource. For example, "ntfr".
   - Click the target systems in the **Available Systems** box.
   - Click the right arrow to move the systems to the **Systems for Service Group** table. To remove a system from the table, click the system and click the left arrow.
   - Select the **Startup** check box to add the systems to the service groups AutoStartList attribute. This enables the service group to automatically come online on a system every time HAD is started.
   - The priority number (starting with 0) is assigned to indicate the order of systems on which the service group will start in case of a failover. If
necessary, double-click the entry in the **Priority** column to enter a new value.

- Click **Next**.

4 Choose the mode of notification which needs to be configured. Select the check boxes to configure SNMP and/or SMTP (if applicable).

5 In the SNMP Configuration dialog box (if applicable):

   - Click + to create the appropriate number of fields for the SNMP consoles and severity levels. Click - to remove a field.
   - Enter the console and click the severity level from the menu. For example, "snmpserv" and "Information".
   - Enter the SNMP trap port. For example, "162" is the default value.
   - Click **Next**.

6 In the SMTP Configuration dialog box (if applicable):

   - Enter the name of the SMTP server.
   - Click + to create the appropriate number of fields for recipients of the notification and severity levels. Click - to remove a field.
Enter the recipient and click the severity level in the drop-down list box. For example, “admin@example.com” and “Information”.

Click Next.

7 In the NIC Resource Configuration dialog box:

- Click Configure NIC Resource (recommended by Symantec) and proceed to the next step. Otherwise, click Next.
- If necessary, enter the name of the resource.
- Click the icon (…) in the Discover column of the table to find the MACAddress for each system.
- Click OK on the Discover dialog box.
- Click Next.

8 Click the Bring the Notifier Resource Online check box, if desired.

9 Click Next.

10 Click Finish.
Administering logs

The Java Console enables you to customize the log display of messages generated by the engine. In the Logs dialog box, you can set filter criteria to search and view messages, and monitor and resolve alert messages.

To browse the logs for detailed views of each log message, double-click the event’s description. Use the arrows in the VCS Log details pop-up window to navigate backward and forward through the message list.

Customizing the log display

From the Logs dialog box, use the Edit Filters feature to customize the display of log messages.

To customize the display for VCS logs

1. In the VCS Logs tab, click Edit Filters.
2. Enter the filter criteria:
   - Click the types of logs to appear on the message display.
   - From the Logs of list, select the category of log messages to display.
   - From the Named menu, select the name of the selected object or component. To view all the messages for the selected category, click All.
Administering logs

- In the **Logs from last** field, enter the numerical value and select the time unit.
- To search log messages, enter the search string. Select the **Whole String** check box, if required.
- Click **OK**.

To customize the display for agent logs

1. In the **Agent Logs** tab, enter the filter criteria:
   - Click the name of the system.
   - Enter the number of logs to view.
   - Click the resource type.
   - Click the name of the resource. To view messages for all resources, click **All**.
   - Click **Get Logs**.

Resetting the log display

Use the **Reset Filters** feature to set the default settings for the log view. For example, if you customized the log view to only show critical and error messages using the **Edit Filters** feature, the **Reset Filters** feature will set the view to show all log messages.

To reset the default settings for the log display

In the **VCS Logs** tab, click **Reset Filters**.
Monitoring alerts

The Java Console sends automatic alerts that require administrative action and are displayed on the Alerts tab of the Logs dialog box. Use this tab to take action on the alert or delete the alert.

**To take action on an alert**

1. In the Alert tab or dialog box, click the alert to take action on.

2. Click **Take Action**.

3. Enter the required information to resolve the alert.
   - If the alert warns that a local group cannot fail over to any system in the local cluster, you cannot take any action.
   - If the alert warns that a global group cannot fail over, the action involves bringing the group online on another system in the global cluster environment.
   - If the alert warns that a global cluster is faulted, the action involves declaring the cluster as a disaster, disconnect, or outage, and determining the service groups to fail over to another cluster.

4. Click **OK**.
To delete an alert

1. In the **Alert** tab or dialog box, click the alert to delete.

2. Click **Delete Alert**.

3. Provide the details for this operation:
   - Enter the reason for deleting the alert.
   - Click **OK**.
VCS Simulator enables you to view state transitions, experiment with configuration parameters, and predict how service groups will behave during cluster or system faults. Use this tool to create and save configurations in an OFFLINE state.

Through the Java Console, VCS Simulator enables you to configure a simulated cluster panel, bring a system in an unknown state into an online state, simulate power loss for running systems, simulate resource faults, and save the configuration while VCS is offline.

For global clusters, you can simulate the process of generating and clearing cluster faults.

You can run multiple simulated clusters on a system by using different port numbers for each cluster. The Java Console provides the same views and features that are available for online configurations.

See "Predicting VCS behavior using VCS Simulator" on page 457.

About administering VCS from the command line

This chapter describes commonly used VCS commands. For more information about specific commands or their options, see their usage information or the man pages associated with the commands.

Most commands can be entered from any system in the cluster when VCS is running. The command to start VCS is typically invoked at system startup. See also “VCS command line reference” on page 632.

Note: On Windows Server 2008, if User Access Control (UAC) is enabled and configured, all VCS commands must be run in the Run as administrator mode. To launch the command prompt in the administrator mode, right-click the command prompt shortcut from the Windows Start menu and click Run as administrator from the context menu. See the Microsoft documentation for more information on UAC.

About the symbols used in the VCS command syntax

Table 8-1 specifies the symbols used in the VCS commands. Do not use these symbols when you run the commands.

Table 8-1  Symbols used in the VCS commands

<table>

Administering the cluster from the command line

About administering VCS from the command line

How VCS identifies the local system

VCS uses the system’s node name. To view the system’s node name from the command line, type:

```
C:\> hostname
```

To view the system’s node name from the desktop

1. Right-click My Computer to display the pop-up menu.
2. Click Properties. The name of the system is listed in the Computer Name tab.

About specifying values preceded by a dash (-)

When specifying values in a command-line syntax, you must prefix values beginning with a dash (-) with a percentage sign (%). If a value begins with a percentage sign, you must prefix it with another percentage sign. (The initial percentage sign is stripped by HAD and does not appear in the configuration file.)

About the -modify option

Most configuration changes are made using the -modify options of the commands haclus, hagrp, hares, hasys, and hatype. Specifically, the -modify option of these commands changes the attribute values stored in the VCS configuration file. By default, all attributes are global, meaning that the value of the attribute is the same for all systems.

**Note:** VCS must be in read/write mode before you can change the configuration. For instructions, see “Setting the configuration to read/write” on page 269.

Encrypting VCS passwords

Use the vcsencrypt utility to encrypt passwords when editing the VCS configuration file main.cf to add VCS users.

---

### Table 8-1: Symbols used in the VCS commands

<table>
<thead>
<tr>
<th>Symbols</th>
<th>Usage</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&gt;</td>
<td>Used in the command help or usage output to specify that these variables must be replaced with the actual values.</td>
<td>haclus -help VCS INFO V-16-1-10601 Usage: haclus -add &lt;cluster&gt; &lt;ip&gt; haclus -delete &lt;cluster&gt;</td>
</tr>
</tbody>
</table>
About administering VCS from the command line

Note: Do not use the `vcsencrypt` utility when entering passwords from the Java and Web consoles.

To encrypt a password

1. Run the utility from the command line.
   ```
   vcsencrypt -vcs
   ```
2. The utility prompts you to enter the password twice. Enter the password and press Return.
   ```
   Enter New Password:
   Enter Again:
   ```
3. The utility encrypts the password and displays the encrypted password. Use the displayed password to edit the VCS configuration file `main.cf`.

Encrypting agent passwords

Use the `vcsencrypt` utility to encrypt passwords when editing the VCS configuration file `main.cf` when configuring agents that require user passwords.

Note: Do not use the `vcsencrypt` utility when entering passwords from the Java and Web consoles.

To encrypt an agent password

1. Run the utility from the command line.
   ```
   vcsencrypt -agent
   ```
2. The utility prompts you to enter the password twice. Enter the password and press Return.
   ```
   Enter New Password:
   Enter Again:
   ```
3. The utility encrypts the password and displays the encrypted password. Use the displayed password to edit the VCS configuration file `main.cf`.

Starting VCS

When VCS is started, it checks the state of its local configuration file and registers with GAB for cluster membership. If the local configuration is valid, and if no other system is running VCS, it builds its state from the local configuration file and enters the RUNNING state.

If the configuration on all nodes is invalid, the VCS engine waits for manual intervention, or for VCS to be started on a system that has a valid configuration.

See “Cluster and system states” on page 737.

To start VCS
◆ Run the following command:

hastart

To start VCS when all systems are in the ADMIN_WAIT state
◆ Run the following command from any system in the cluster to force VCS to use the configuration file from the system specified by the variable system:

hasys -force system

To start VCS on a single node
◆ Type the following command to start an instance of VCS that does not require the GAB and LLT packages. Do not use this command on a multisystem cluster.

hastart -onenode
To start CommandServer

- Run the following command:
  net start cmdserver

Stopping VCS

The `hastop` command stops HAD and related processes. You can customize the behavior of the `hastop` command by configuring the EngineShutdown attribute for the cluster.

See "Controlling the `hastop` behavior using the EngineShutdown attribute" on page 266.

The `hastop` command includes the following options:

```
  hastop -all [-force]
  hastop [-help]
  hastop -local [-force | -evacuate | -noautodisable]
  hastop -sys system ... [-force | -evacuate | -noautodisable]
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-all</td>
<td>Stops HAD on all systems in the cluster and takes all service groups offline.</td>
</tr>
<tr>
<td>-help</td>
<td>Displays command usage.</td>
</tr>
<tr>
<td>-local</td>
<td>Stops HAD on the system on which you typed the command</td>
</tr>
<tr>
<td>-force</td>
<td>Allows HAD to be stopped without taking service groups offline on the system. The value of the EngineShutdown attribute does not influence the behavior of the -force option.</td>
</tr>
<tr>
<td>-evacuate</td>
<td>When combined with -local or -sys, migrates the system's active service groups to another system in the cluster, before the system is stopped.</td>
</tr>
<tr>
<td>-noautodisable</td>
<td>Ensures that service groups that can run on the node where the hastop command was issued are not autodisabled. This option can be used with -evacuate but not with -force.</td>
</tr>
<tr>
<td>-sys</td>
<td>Stops HAD on the specified system.</td>
</tr>
</tbody>
</table>

Stopping VCS without -force option

When VCS is stopped on a system without using the -force option, it enters the LEAVING state, and waits for all groups to go offline on the system. Use the
output of the command `hasys -display system` to verify that the values of the SysState and the OnGrpCnt attributes are non-zero. VCS continues to wait for the service groups to go offline before it shuts down.

See “Troubleshooting resources” on page 702.

**Stopping VCS with options other than -force**

When VCS is stopped by options other than `-force` on a system with online service groups, the groups running on the system are taken offline and remain offline. This is indicated by VCS setting the attribute IntentOnline to 0. Using the option `-force` enables service groups to continue running while the VCS engine (HAD) is brought down and restarted. The value of the IntentOnline attribute remains unchanged after the VCS engine restarts.

**Controlling the hastop behavior using the EngineShutdown attribute**

Use the EngineShutdown attribute to define VCS behavior when a user runs the hastop command.

<table>
<thead>
<tr>
<th>EngineShutdown Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>Process all hastop commands. This is the default behavior.</td>
</tr>
<tr>
<td>Disable</td>
<td>Reject all hastop commands.</td>
</tr>
<tr>
<td>DisableClusStop</td>
<td>Do not process the hastop -all command; process all other hastop commands.</td>
</tr>
<tr>
<td>PromptClusStop</td>
<td>Prompt for user confirmation before running the hastop -all command; process all other hastop commands.</td>
</tr>
<tr>
<td>PromptLocal</td>
<td>Prompt for user confirmation before running the hastop -local command; process all other hastop commands.</td>
</tr>
<tr>
<td>PromptAlways</td>
<td>Prompt for user confirmation before running any hastop command.</td>
</tr>
</tbody>
</table>

**Note:** VCS does not consider this attribute when the hastop is issued with the following options: `-force` or `-local` `-evacuate` `-noautodisable`. Configure one of the following values for the attribute depending on the desired functionality for the hastop command:
Additional considerations for stopping VCS

- If using the command `reboot`, behavior is controlled by the `ShutdownTimeOut` parameter. After HAD exits, if GAB exits within the time designated in the `ShutdownTimeout` attribute, the remaining systems recognize this as a reboot and fail over service groups from the departed system. For systems running several applications, consider increasing the value in the `ShutdownTimeout` attribute.

- Stopping VCS on a system autodisables each service group that includes the system in their `SystemList` attribute. (This does not apply to systems that are powered off.)

- If you use the `-evacuate` option, evacuation occurs before VCS is brought down.
Managing VCS configuration files

This section describes how to verify, back up, and restore VCS configuration files.

See "About the main.cf file" on page 53.
See "The types.cf file" on page 55.

About the hacf utility

The hacf utility translates the VCS configuration language into a syntax that can be read by the VCS engine. Specifically, hacf translates the contents of the main configuration file, main.cf, into commands for the VCS server.

The hacf utility verifies the configuration before loading it into VCS. The configuration is not loaded under the following conditions:

- If main.cf or include files are missing.
- If syntax errors appear in the .cf files.
- If the configuration file is invalid.

See “Setting the configuration to read/write” on page 269.

About multiple versions of .cf files

When hacf creates a .cf file, it does not overwrite existing .cf files. A copy of the file remains in the directory, and its name includes a suffix of the date and time it was created, such as main.cf.03Dec2001.175904. In addition, the previous version of any .cf file is saved with the suffix .previous; for example, main.cf.previous.

Verifying a configuration

Use hacf to verify (check syntax of) the main.cf and the type definition file, types.cf. VCS does not execute if hacf detects errors in the configuration.

To verify a configuration

- Run the following command:
  
  hacf -verify config_directory

  The variable config_directory refers to directories containing a main.cf file and any .cf files included in main.cf.

  No error message and a return value of zero indicates that the syntax is legal.
Scheduling automatic backups for VCS configuration files

Configure the BackupInterval attribute to instruct VCS to create a back up of the configuration periodically. VCS backs up the main.cf and types.cf files as main.cf.autobackup and types.cf.autobackup respectively.

To start periodic backups of VCS configuration files
◆ Set the cluster-level attribute BackupInterval to a non-zero value. For example, to back up the configuration every 5 minutes, set BackupInterval to 5.

Saving a configuration

When you save a configuration, VCS renames the file main.cf.autobackup to main.cf. VCS also save your running configuration to the file main.cf.autobackup.

If have not configured the BackupInterval attribute, VCS saves the running configuration.

See “Scheduling automatic backups for VCS configuration files” on page 269.

To save a configuration
◆ Run the following command
  haconf -dump -makero
  The option -makero sets the configuration to read-only.

Setting the configuration to read/write

To set the mode to read/write
◆ Type the following command:
  haconf -makerw

Formatting configuration files

When you manually edit VCS configuration files (for example, the main.cf or types.cf file) you can potentially create formatting issues that prevent the files from being parsed correctly.

To display the configuration files in the correct format
◆ Run the following commands to display the configuration files in the correct format:
  # hacf -cftocmd config
  # hacf -cmdtocf config
Administering the cluster from the command line

Managing VCS configuration files

Taking snapshots of VCS configuration files

Use the hasnap command to take snapshots of VCS configuration files on each node in the cluster. You can also restore the configuration from a snapshot.

The command includes the following options; each option is described in detail in the following sections:

- **hasnap -backup** Backs up files in a snapshot format.
- **hasnap -restore** Restores a previously created snapshot.
- **hasnap -display** Displays details of previously created snapshots.
- **hasnap -sdiff** Displays files that were changed on the local system after a specific snapshot was created.
- **hasnap -fdiff** Displays the differences between a file in the cluster and its copy stored in a snapshot.
- **hasnap -export** Exports a snapshot from the local, predefined directory to the specified file.
- **hasnap -include** Configures the list of files or directories to be included in new snapshots, in addition to those included automatically by the -backup command.
- **hasnap -exclude** Configures the list of files or directories to be excluded from new snapshots when backing up the configuration using the -backup command.
- **hasnap -delete** Deletes snapshots from the predefined local directory on each node.

**Note:** With the exception of the -include, -exclude, and the -delete options, all options can be combined with the -f option. This option indicates that all files be backed up to or restored from the specified single file instead of a local, predefined directory on each node. This option is useful when you want to store the configuration data to an alternate location that is periodically backed up using backup software like Veritas Net Backup.
Backing up configuration files
The `hasnap -backup` command backs up files in a snapshot format. A snapshot is a collection of VCS configuration files backed up at a particular point in time, typically before making changes to the existing configuration. A snapshot also contains information such as the snapshot name, description, creation time, and file permissions.

The command backs up a predefined list of VCS configuration files as well as a user-defined list. The predefined list includes all the *.cf files, custom agents, LLT and GAB configuration files, triggers, custom heartbeats, and action scripts. See the `-include` and `-exclude` commands to construct a user-defined list.

To back up VCS configuration files
◆ Run the following command

```bash
dshell> hasnap -backup [-f filename] [-n] [-m description]
```

Use the `-n` option to run the command in the non-interactive mode.
Use the `-m` option to specifies a description of the snapshot.

Examples
The following command creates a backup of the configuration in the non-interactive mode and adds Test Backup as the backup description.

```bash
dshell> hasnap -backup -n -m "Test Backup"
```

Restoring VCS configuration files
The `hasnap -restore` command restores configuration files from a previously created snapshot.

To restore VCS configuration files
◆ Run the following command:

```bash
dshell> hasnap -restore [-f filename] [-n] [-s snapid]
```

- `-n`  Run the command in the non-interactive mode.
- `-s`  option to specifies the ID of the snapshot to be restored.

If you do not specify a snapshot ID, the command lists the snapshots that are available for restoration.

Examples
The following command restores the snapshot vcs-20030101-22232 in the non-interactive mode.

```bash
dshell> hasnap -restore -n -s vcs-20030101-22232
```
Viewing snapshots of configuration files

Use the `hasnap -display` command to view details of previously created snapshots.

To view snapshots of configuration files

```
hasnap -display [-f filename] [-list|-s snapid] [-m] [-l] [-t]
```

- `list` — Displays the list of snapshots in the repository.
- `-s` — Specifies the snapshot ID.
- `-m` — Displays snapshot description.
- `-l` — Lists files in the snapshot
- `-t` — Displays the snapshot timestamp

If no options are specified, the command displays all information about the latest snapshot.

Examples

The following command lists all snapshots.

```
hasnap -display -list
```

The following command displays the description and the time of creation of the specified snapshot.

```
hasnap -display -s vcs-20030101-2232 -m -t
```

Viewing files changed after a snapshot

Use the `hasnap -sdiff` command to display files that were changed on the local system after a specific snapshot was created.

To view files that changed after a snapshot

◆ Run the following command:

```
hasnap -sdiff [-f filename] [-s snapid] [-sys hostname]
```

- `-s` — Identifies the snapshot ID of the comparison snapshot.
- `-sys` — Indicates the host on which the snapshot is to be compared.

If you do not specify any options, the command uses the latest snapshot to compare the files on each node in the cluster.
Administering the cluster from the command line

Managing VCS configuration files

Examples
The following command displays the differences between the current configuration and the snapshot vcs-20030101-22232.

```
hasnap -sdiff -s vcs-20030101-22232
```

Comparing a file with its snapshot copy

Use the `hasnap -fdiff` to display differences between a file on the cluster and its copy stored in a previously created snapshot.

To compare a file with its snapshot copy

- Run the following command:

```
hasnap -fdiff [-f filename] [-s snapid] [-sys hostname] file
```

- `-s` Specifies the ID of the snapshot.
- `-sys` Specifies the host on which the snapshot is to be compared.
- `-file` The file to compare.

If you do not specify any options, the command uses the latest snapshot to compare the file on each node in the cluster.
Exporting snapshots

Use the `hasnap -export` command to export a snapshot from the local, predefined directory on each node in the cluster to a specified file. This option is useful when you want to store a previously created snapshot to an alternate location that is periodically backed up using backup software like Veritas NetBackup.

To export a snapshot

Run the following command:

```
hasnap -export -f filename [-s snapid]
```

- `-s` Specifies the ID of the snapshot.
- `-f` Specifies the file.

If you do not specify a snapshot ID, the command exports the latest snapshot to the specified file.
Adding and removing files for snapshots

Use the *hasnap -include* command to configure the list of files or directories to be included in new snapshots. This list is in addition to the files included by the *-backup* command.

See "Backing up configuration files" on page 271.

To add or remove files for a snapshot:

- Run the following command:
  ```bash
  hasnap -include -add|-del|-list [-sys hostname] files|directories
  ```

  - **-add** Adds the specified files or directories to the include file list.
  - **-del** Removes the specified files or directories from the include file list.
  - **files/directories** Files or directories to be added or removed.

Examples

The following command displays the list of files or directories to be included in new snapshots on each node of the cluster.

```
hasnap -include -list
```

Excluding files from snapshots

Use the *hasnap -exclude* command to configure the list of files or directories that should not be included in new snapshots.

To exclude files from snapshots:

- Run the following command:
  ```bash
  hasnap -exclude -add|-del|-list [-sys hostname] files|directories
  ```

  - **-add** Adds the specified files or directories to the exclude file list.
  - **-del** Removes the specified files or directories from the exclude file list.
  - **files/directories** Files or directories to be added or removed.

Examples

The following command displays the exclude file list on each node in the cluster.

```
hasnap -exclude -list
```
Deleting snapshots

Use the `hasnap -delete` command to delete snapshots from the predefined local directory on each node.

To delete a snapshot

Run the following command:

```
hasnap -delete [-s snapid]
```

- `-s` Specifies the ID of the snapshot to be deleted.

If you do not specify the snapshot ID, the command lists the snapshots that can be deleted.

Example

The following command deletes snapshot `vcs-20030101-22232` from the cluster.

```
hasnap -delete -s vcs-20030101-22232
```
Managing VCS users from the command line

You can add, modify, and delete users on any system in the cluster, provided you have the privileges to do so.

If VCS is running in secure mode, specify fully-qualified user names, in the format username@domain. You cannot assign or change passwords for users when VCS is running in secure mode.

The commands to add, modify, and delete a user must be executed only as root or administrator and only if the VCS configuration is in read/write mode.

See “Setting the configuration to read/write” on page 269.

**Note:** You must add users to the VCS configuration to monitor and administer VCS from the graphical user interface Cluster Manager.

Adding a user

Users in the category Cluster Guest cannot add users.

**To add a user**

1. Set the configuration to read/write mode:
   
   `haconf -makerw`

2. Add the user:
   
   `hauser -add user [-priv <Administrator|Operator> [-group service_groups]]`

3. Enter a password when prompted.

4. Reset the configuration to read-only:
   
   `haconf -dump -makero`

**To add a user with cluster administrator access**

◆ Type the following command:

   `hauser -add user -priv Administrator`

**To add a user with cluster operator access**

◆ Type the following command:

   `hauser -add user -priv Operator`

**To add a user with group administrator access**

◆ Type the following command:

   `hauser -add user -priv Administrator -group service_groups`
To add a user with group operator access
◆ Type the following command:
  hauser -add user -priv Operator -group service_groups

Assigning and removing user privileges

To assign privileges to an administrator or operator
◆ Type the following command:
  hauser -addpriv user Administrator|Operator
     [-group service_groups]

To remove privileges from an administrator or operator
◆ Type the following command:
  hauser -delpriv user Administrator|Operator
     [-group service_groups]

To assign privileges to an OS user group
◆ Type the following command:
  hauser -addpriv usergroup AdministratorGroup|OperatorGroup
     [-group service_groups]

To remove privileges from an OS user group
◆ Type the following command:
  hauser -delpriv usergroup AdministratorGroup|OperatorGroup
     [-group service_groups]

Modifying a user

Users in the category Cluster Guest cannot modify users.

To modify a user
1 Set the configuration to read/write mode:
   haconf -makerw
2 Modify the user:
   hauser -update user
3 Enter a new password when prompted.
4 Reset the configuration to read-only:
   haconf -dump -makero
Deleting a user

You can delete a user from the VCS configuration.

To delete a user
1. Set the configuration to read/write mode:
   ```
   haconf -makerw
   ```
2. For users with Administrator and Operator access, remove their privileges:
   ```
   hauser -delpriv user Administrator|Operator [-group service_groups]
   ```
3. Delete the user from the list of registered users:
   ```
   hauser -delete user
   ```
4. Reset the configuration to read-only:
   ```
   haconf -dump -makero
   ```

Displaying a user

Display a list of users and their privileges.

To display a list of users
◆ Type the following command:
   ```
   hauser -list
   ```

To display the privileges of all users
◆ Type the following command:
   ```
   hauser -display
   ```

To display the privileges of a specific user
◆ Type the following command:
   ```
   hauser -display user
   ```
Querying VCS

VCS enables you to query various cluster objects, including resources, service groups, systems, resource types, agents, and clusters. You may enter query commands from any system in the cluster. Commands to display information on the VCS configuration or system states can be executed by all users: you do not need root privileges.

Querying service groups

To display the state of a service group on a system
◆ Type the following command:
  
  \texttt{hagrp -state [service\_group] [-sys system]}

To display the resources for a service group
◆ Type the following command:
  
  \texttt{hagrp -resources service\_group}

To display a list of a service group's dependencies
◆ Type the following command:
  
  \texttt{hagrp -dep [service\_group]}

To display a service group on a system
◆ Type the following command:
  
  \texttt{hagrp -display [service\_group] [-sys system]}
  
  If \texttt{service\_group} is not specified, information regarding all service groups is displayed.

To display attributes of a system
◆ Type the following command:
  
  \texttt{hagrp -display [service\_group] [-attribute attribute] [-sys system]}

  Note that system names are case-sensitive.
Querying resources

To display a resource's dependencies
◆ Type the following command:
  ```bash
  hares -dep [resource]
  ```

To display information about a resource
◆ Type the following command:
  ```bash
  hares -display [resource]
  ```
  If `resource` is not specified, information regarding all resources is displayed.

To confirm an attribute's values are the same on all systems
◆ Type the following command:
  ```bash
  hares -global resource attribute value ... | key... | (key value)...```

To display resources of a service group
◆ Type the following command:
  ```bash
  hares -display -group service_group```

To display resources of a resource type
◆ Type the following command:
  ```bash
  hares -display -type resource_type```

To display attributes of a system
◆ Type the following command:
  ```bash
  hares -display -sys system```
Querying resource types

To display all resource types
◆ Type the following command:
   `hatype -list`

To display resources of a particular resource type
◆ Type the following command:
   `hatype -resources resource_type`

To display information about a resource type
◆ Type the following command:
   `hatype -display resource_type`
   If `resource_type` is not specified, information regarding all types is displayed.

Querying agents

To display the run-time status of an agent
◆ Type the following command:
   `haagent -display [agent]`
   If `agent` is not specified, information regarding all agents is displayed.

Run-Time Status Definition

<table>
<thead>
<tr>
<th>Status</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faults</td>
<td>Indicates the number of agent faults and the time the faults began.</td>
</tr>
<tr>
<td>Messages</td>
<td>Displays various messages regarding agent status.</td>
</tr>
<tr>
<td>Running</td>
<td>Indicates the agent is operating.</td>
</tr>
<tr>
<td>Started</td>
<td>Indicates the file is executed by the VCS engine (HAD).</td>
</tr>
</tbody>
</table>
Querying systems

To display a list of systems in the cluster
◆ Type the following command:

```
hasys -list
```

To display information about each system
◆ Type the following command:

```
hasys -display [system]
```

Querying clusters

To display the value of a specific cluster attribute
◆ Type the following command:

```
haclus -value attribute
```

To display information about the cluster
◆ Type the following command:

```
haclus -display
```

Querying status

To display the status of all service groups in the cluster, including resources
◆ Type the following command:

```
hastatus
```

To display the status of a particular service group, including its resources
◆ Type the following command:

```
hastatus [-sound] -group service_group [-group service_group]...
```

If you do not specify a service group, the status of all service groups is displayed. The \(-\text{sound}\) option enables a bell to ring each time a resource faults.

To display the status of service groups and resources on specific systems
◆ Type the following command:

```
hastatus [-sound] -sys system_name [-sys system_name]...
```

To display the status of specific resources
◆ Type the following command:
Querying VCS

% hastatus [-sound] -resource resource_name [-resource resource_name]...

To display the status of cluster faults, including faulted service groups, resources, systems, links, and agents
◆ Type the following command:
  hastatus -summary

**Note:** Unless executed with the -summary options, the hastatus command continues to produce output of online state transitions until you interrupt it with the command CTRL+C.

Querying log data files (LDFs)

Log data files (LDFs) contain data regarding messages written to a corresponding English language file. Typically, for each English file there is a corresponding LDF.

To display the hamsg usage list
◆ Type the following command:
  hamsg -help

To display the list of LDFs available on the current system
◆ Type the following command:
  hamsg -list

To display general LDF data
◆ Type the following command:
  hamsg -info [-path path_name] LDF
  The option -path specifies where hamsg looks for the specified LDF. If not specified, hamsg looks for files in the default directory:
  Program Files\VERITAS\Cluster Server\ldf

To display specific LDF data
◆ Type the following command:
  hamsg [-any] [-sev C|E|W|N|I] [-otype VCS|RES|GRP|SYS|AGT]
  [-oname object_name] [-msgid message_ID] [-path path_name] [-lang language] LDF
Administering the cluster from the command line

---

Querying VCS

- `any` Specifies `hams` return messages matching any of the specified query options.

- `sev` Specifies `hams` return messages matching the specified message severity Critical, Error, Warning, Notice, or Information.

- `otype` Specifies `hams` return messages matching the specified object type
  - VCS = general VCS messages
  - RES = resource
  - GRP = service group
  - SYS = system
  - AGT = agent

- `oname` Specifies `hams` return messages matching the specified object name.

- `msgid` Specifies `hams` return messages matching the specified message ID.

- `path` Specifies where `hams` looks for the specified LDF. If not specified, `hams` looks for files in the default directory `/var/VRTSvcs/ldf`.

- `lang` Specifies the language in which to display messages. For example, the value `en` specifies English and `ja` specifies Japanese.
Using conditional statements to query VCS objects

Some query commands include an option for conditional statements. Conditional statements take three forms:
- `Attribute=Value` (the attribute equals the value)
- `Attribute!=Value` (the attribute does not equal the value)
- `Attribute=~Value` (the value is the prefix of the attribute, for example a query for the state of a resource = ~FAULTED returns all resources whose state begins with FAULTED.)

Multiple conditional statements can be used and imply AND logic.

You can only query attribute-value pairs displayed in the output of the command `hagrp -display`.

See “Querying service groups” on page 280.

To display the list of service groups whose values match a conditional statement

◆ Type the following command:

```
hagrp -list [conditional_statement]
```

If no conditional statement is specified, all service groups in the cluster are listed.

To display a list of resources whose values match a conditional statement

◆ Type the following command:

```
hares -list [conditional_statement]
```

If no conditional statement is specified, all resources in the cluster are listed.

To display a list of agents whose values match a conditional statement

◆ Type the following command:

```
haagent -list [conditional_statement]
```

If no conditional statement is specified, all agents in the cluster are listed.
Administering service groups
This section describes how to add, delete, and modify service groups. It also describes how to perform service group operations from the command line.

Adding and deleting service groups

To add a service group to your cluster

```bash
hagrp -add service_group
```

The variable `service_group` must be unique among all service groups defined in the cluster.

This command initializes a service group that is ready to contain various resources. To employ the group properly, you must populate its SystemList attribute to define the systems on which the group may be brought online and taken offline. (A system list is an association of names and integers that represent priority values.)

To delete a service group

◆ Type the following command:

```bash
hagrp -delete service_group
```

Note that you cannot delete a service group until all of its resources are deleted.

Modifying service group attributes

To modify a service group attribute

◆ Type the following command:

```bash
hagrp -modify service_group attribute value [-sys system]
```

The variable `value` represents:

```
  system_name1 priority system_name2 priority2
```

If the attribute being modified has local scope, you must specify the system on which to modify the attribute, except when modifying the attribute on the system from which you run the command.

For example, to populate the system list of service group groupx with Systems A and B, type:

```bash
hagrp -modify groupx SystemList -add SystemA 1 SystemB 2
```

Similarly, to populate the AutoStartList attribute of a service group, type:

```bash
hagrp -modify groupx AutoStartList SystemA SystemB
```
You may also define a service group as parallel. To set the Parallel attribute to 1, type the following command. (Note that the default for this attribute is 0, which designates the service group as a failover group.):

```
hagrp -modify groupx Parallel 1
```

This attribute cannot be modified if resources have already been added to the service group.

You can modify the attributes SystemList, AutoStartList, and Parallel only by using the command `hagrp -modify`. You cannot modify attributes created by the system, such as the state of the service group.

**About modifying the SystemList attribute**

When using the `hagrp -modify` command to change a service group's existing system list, you can use the options `-modify`, `-add`, `-update`, `-delete`, or `-delete -keys`.

For example, suppose you originally defined the SystemList of service group groupx as SystemA and SystemB. Then after the cluster was brought up you added a new system to the list:

```
hagrp -modify groupx SystemList -add SystemC 3
```

You must take the service group offline on the system being modified.

When you add a system to a service group's system list, the system must have been previously added to the cluster. When using the command line, you can use the `hasys -add` command.

When you delete a system from a service group's system list, the service group must not be online on the system to be deleted.

If you attempt to change a service group's existing system list using `hagrp -modify` without other options (such as `-add` or `-update`) the command fails.
Bringing service groups online

To bring a service group online

◆ Type the following command:

\texttt{hagrp -online service\_group -sys system}

To start a service group on a system and bring online only the resources already online on another system

◆ Type the following command:

\texttt{hagrp -online service\_group -sys system -checkpartial other\_system}

If the service group does not have resources online on the other system, the service group is brought online on the original system and the checkpartial option is ignored.

Note that the checkpartial option is used by the Preonline trigger during failover. When a service group configured with Preonline =1 fails over to another system (system 2), the only resources brought online on system 2 are those that were previously online on system 1 prior to failover.

Taking service groups offline

To take a service group offline

◆ Type the following command:

\texttt{hagrp -offline service\_group -sys system}

To take a service group offline only if all resources are probed on the system

◆ Type the following command:

\texttt{hagrp -offline [-ifprobed] service\_group -sys system}

Switching service groups

The process of switching a service group involves taking it offline on its current system and bringing it online on another system

To switch a service group from one system to another

◆ Type the following command:

\texttt{hagrp -switch service\_group -to system}

A service group can be switched only if it is fully or partially online. The -switch option is not supported for switching hybrid service groups across system zones.
Switch parallel global groups across cluster using the following command:

```
hagrp -switch service_group -any -clus remote_cluster
```
VCS brings the parallel service group online on all possible nodes in the remote cluster.

Freezing and unfreezing service groups

Freeze a service group to prevent it from failing over to another system. This freezing process stops all online and offline procedures on the service group.

Unfreeze a frozen service group to perform online or offline operations on the service group.

**To freeze a service group (disable online, offline, and failover operations)**

- Type the following command:
  ```
hagrp -freeze service_group [-persistent]
```
  The option `-persistent` enables the freeze to be remembered when the cluster is rebooted.

**To unfreeze a service group (reenable online, offline, and failover operations)**

- Type the following command:
  ```
hagrp -unfreeze service_group [-persistent]
```

Enabling and disabling service groups

Enable a service group before bringing it online. A service group that was manually disabled during a maintenance procedure on a system may need to be brought online after the procedure is completed.

Disable a service group to prevent it from coming online. This process temporarily stops VCS from monitoring a service group on a system undergoing maintenance operations.

**To enable a service group**

- Type the following command:
  ```
hagrp -enable service_group [-sys system]
```
  A group can be brought online only if it is enabled.

**To disable a service group**

- Type the following command:
  ```
hagrp -disable service_group [-sys system]
```
  A group cannot be brought online or switched if it is disabled.
Administering the cluster from the command line

Administering service groups

To enable all resources in a service group
◆ Type the following command:
   
   `hagrp -enableresources service_group`

To disable all resources in a service group
◆ Type the following command:
   
   `hagrp -disableresources service_group`

Agents do not monitor group resources if resources are disabled.

Clearing faulted resources in a service group
Clear a resource to remove a fault and make the resource available to go online.

To clear faulted, non-persistent resources in a service group
◆ Type the following command:
   
   `hagrp -clear service_group [-sys system]
   Clearing a resource initiates the online process previously blocked while waiting for the resource to become clear.
   ■ If `system` is specified, all faulted, non-persistent resources are cleared from that system only.
   ■ If `system` is not specified, the service group is cleared on all systems in the group’s SystemList in which at least one non-persistent resource has faulted.

To clear resources in ADMIN_WAIT state in a service group
◆ Type the following command:
   
   `hagrp -clearadminwait [-fault] service_group -sys system`

Linking and unlinking service groups
Link service groups to create a dependency between them.
See “About service group dependencies” on page 518.

To link service groups
◆ Type the following command
   
   `hagrp -link parent_group child_group gd_category gd_location gd_type`

   `parent_group` Name of the parent group

   `child_group` Name of the child group
To unlink service groups
◆ Type the following command:
  
  hagrp -unlink parent_group child_group

Administering agents

Under normal conditions, VCS agents are started and stopped automatically.

To start an agent
◆ Run the following command:
  
  haagent -start agent -sys system

To stop an agent
◆ Run the following command:
  
  haagent -stop agent [-force] -sys system

The -force option stops the agent even if the resources for the agent are online. Use the -force option when you want to upgrade an agent without taking its resources offline.

gd_category  Category of group dependency (online/offline).
gd_location  The scope of dependency (local/global/remote).
gd_type  Type of group dependency (soft/firm/hard). Default is firm.
Administering resources

About adding resources

When you add a resource, all non-static attributes of the resource’s type, plus their default values, are copied to the new resource.

Three attributes are also created by the system and added to the resource:

- Critical (default = 1). If the resource or any of its children faults while online, the entire service group is marked faulted and failover occurs.
- AutoStart (default = 1). If the resource is set to AutoStart, it is brought online in response to a service group command. All resources designated as AutoStart=1 must be online for the service group to be considered online. (This attribute is unrelated to AutoStart attributes for service groups.)
- Enabled. If the resource is set to Enabled, the agent for the resource’s type manages the resource. The default is 1 for resources defined in the configuration file main.cf, 0 for resources added on the command line.

Note: Adding resources on the command line requires several steps, and the agent must be prevented from managing the resource until the steps are completed. For resources defined in the configuration file, the steps are completed before the agent is started.

Adding resources

Add resource to a service group or remove resources from a service group.

To add a resource

- Type the following command:

```bash
hares -add resource resource_type service_group
```

The resource name must be unique throughout the cluster. The resource type must be defined in the configuration language. The resource belongs to the group `service_group`.
Deleting resources

Delete resources from a service group.

To delete a resource

◆ Type the following command:

```
# hares -delete resource
```

Adding, deleting, and modifying resource attributes

Resource names must be unique throughout the cluster and you cannot modify resource attributes defined by the system, such as the resource state.

To modify a new resource

◆ Type the following command:

```
# hares -modify resource attribute value
# hares -modify <resource> <attr> <value>
[-sys <system>] [-wait [-time <waittime>]]
```

The variable `value` depends on the type of attribute being created.

To set a new resource’s enabled attribute to 1

◆ Type the following command:

```
# hares -modify resourceA Enabled 1
```

The agent managing the resource is started on a system when its Enabled attribute is set to 1 on that system. Specifically, the VCS engine begins to monitor the resource for faults. Agent monitoring is disabled if the Enabled attribute is reset to 0.

To add a resource attribute

```
# haattr -add resource_type attribute [value] [dimension] [default ...]
```

The variable `value` is a -string (default), -integer, or -boolean.

The variable `dimension` is -scalar (default), -keylist, -assoc, or -vector.

The variable `default` is the default value of the attribute and must be compatible with the `value` and `dimension`. Note that this may include more than one item, as indicated by ellipses (...).

To delete a resource attribute

```
# haattr -delete resource_type attribute
```

To add a static resource attribute
Administering the cluster from the command line

Administering resources

```bash
# haattr -add -static resource_type static_attribute [value]
    [dimension] [default ...]
```

To delete a static resource attribute
```bash
# haattr -delete -static resource_type static_attribute
```

To add a temporary resource attribute
```bash
# haattr -add -temp resource_type attribute [value]
    [dimension] [default ...]
```

To delete a temporary resource attribute
```bash
# haattr -delete -temp resource_type attribute
```

To modify the default value of a resource attribute
```bash
# haattr -default resource_type attribute new_value ...
```

The variable `new_value` refers to the attribute’s new default value.
Defining attributes as local

Localizing an attribute means that the attribute has a per-system value for each system listed in the group’s SystemList. These attributes are localized on a per-resource basis. For example, to localize the attribute `attribute_name` for `resource` only, type:

```
# hares -local resource attribute_name
```

Note that global attributes cannot be modified with the `hares -local` command. The following table lists the commands to be used to localize attributes depending on their dimension.

Table 8-2  Making VCS attributes local

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Task and Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>scalar</td>
<td>Replace a value:</td>
</tr>
<tr>
<td></td>
<td>-modify [object] attribute_name value [-sys system]</td>
</tr>
<tr>
<td>vector</td>
<td><img src="https://example.com/operations" alt="List operations" /></td>
</tr>
<tr>
<td>keylist</td>
<td><img src="https://example.com/operations" alt="Keylist operations" /></td>
</tr>
</tbody>
</table>
Administering the cluster from the command line

Administering resources

Table 8-2 Making VCS attributes local

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Task and Command</th>
</tr>
</thead>
</table>
| association | Replace list of key-value pairs (duplicate keys not allowed):  
-modify [object] attribute_name value ... [-sys system]  
- Add user-supplied list of key-value pairs to existing list (duplicate keys not allowed):  
-modify [object] attribute_name -add value ...[-sys system]  
- Replace value of each key with user-supplied value:  
-modify [object] attribute_name -update key value ... [-sys system]  
- Delete a key-value pair identified by user-supplied key:  
-modify [object] attribute_name -delete key ... [-sys system]  
- Delete all key-value pairs from association:  
-modify [object] attribute_name -delete -keys [-sys system]  

Note: If multiple values are specified and if one is invalid, VCS returns an error for the invalid value, but continues to process the others. In the following example, if sysb is part of the attribute SystemList, but sysa is not, sysb is deleted and an error message is sent to the log regarding sysa.

hagrp -modify group1 SystemList -delete sysa sysb [-sys system]
Linking and unlinking resources

Link resources to specify a dependency between them. A resource can have an unlimited number of parents and children. When linking resources, the parent cannot be a resource whose Operations attribute is equal to None or OnOnly. Specifically, these are resources that cannot be brought online or taken offline by an agent (None), or can only be brought online by an agent (OnOnly).

Loop cycles are automatically prohibited by the VCS engine. You cannot specify a resource link between resources of different service groups.

To link resources

◆ Type the following command:

```bash
# hares -link parent_resource child_resource
```

The variable `parent_resource` depends on `child_resource` being online before going online itself. Conversely, `parent_resource` go offline before `child_resource` goes offline.

For example, a NIC resource must be available before an IP resource can go online, so for resources IP1 of type IP and NIC1 of type NIC, specify the dependency as:

```bash
# hares -link IP1 NIC1
```

To unlink resources

◆ Type the following command:

```bash
# hares -unlink parent_resource child_resource
```

Bringing resources online

To bring a resource online

◆ Type the following command:

```bash
# hares -online resource -sys system
```

Taking resources offline

To take a resource offline

◆ Type the following command:

```bash
# hares -offline [-ignoreparent| -parentprop] resource -sys system
```

The option `-ignoreparent` enables a resource to be taken offline even if its parent resources in the service group are online. This option does not work if taking the resources offline violates the group dependency.
Administering the cluster from the command line

Administering resources

To take a resource and its parent resources offline
◆ Type the following command:

```
# has -offline -parentprop resource -sys system
```
The command stops all parent resources in order before taking the specific resource offline.

To take a resource offline and propagate the command to its children
◆ Type the following command:

```
# has -offprop [-ignoreparent] resource -sys system
```
As in the above command, the option `-ignoreparent` enables a resource to be taken offline even if its parent resources in the service group are online. This option does not work if taking the resources offline violates the group dependency.

Probing a resource

To prompt an agent to monitor a resource on a system
◆ Type the following command:

```
# has -probe resource -sys system
```
Though the command may return immediately, the monitoring process may not be completed by the time the command returns.

Clearing a resource

To clear a resource
◆ Type the following command:

```
# has -clear resource [-sys system]
```
Clearing a resource initiates the online process previously blocked while waiting for the resource to become clear. If `system` is not specified, the fault is cleared on each system in the service group’s SystemList attribute. See “To clear faulted, non-persistent resources in a service group” on page 291.
This command also clears the resource’s parents. Persistent resources whose static attribute Operations is defined as None cannot be cleared with this command and must be physically attended to, such as replacing a raw disk. The agent then updates the status automatically.
Administering systems

To modify a system's attributes
◆ Type the following command:
  
  ```
  # hasys -modify modify_options
  ```

  Some attributes are internal to VCS and cannot be modified. For details on system attributes, see "About the -modify option" on page 261.

To display the value of a system's node ID as defined in the file %VCS_ROOT%\comms\llt\llttab.txt
◆ Type the following command:
  
  ```
  # hasys -nodeid node_ID
  ```

To freeze a system (prevent groups from being brought online or switched on the system)
◆ Type the following command:
  
  ```
  # hasys -freeze [-persistent] [-evacuate] system
  ```

  -persistent Enables the freeze to be “remembered” when the cluster is rebooted. Note that the cluster configuration must be in read/write mode and must be saved to disk (dumped) to enable the freeze to be remembered.

  -evacuate Fails over the system's active service groups to another system in the cluster before the freeze is enabled.

To unfreeze a frozen system (reenable online and switch of service groups)
◆ Type the following command:
  
  ```
  # hasys -unfreeze [-persistent] system
  ```

To run a command on any system in a cluster
◆ Type the following command:
  
  ```
  # hacli -cmd command [-sys | -server system(s)]
  ```

  Issues a command to be executed on the specified system(s). VCS must be running on the systems.

  The use of the hacli command requires setting HacliUserLevel to at least COMMANDROOT. By default, the HacliUserLevel setting is NONE.

  If the users do not want the root user on system A to enjoy root privileges on another system B, HacliUserLevel should remain set to NONE (the default) on system B.

  You can specify multiple systems separated by a single space as arguments to the option -sys. If no system is specified, command runs on all systems in
cluster with VCS in a RUNNING state. The command argument must be entered within double quotes if command includes any delimiters or options.

## Administering clusters

### Retrieving version information

Retrieve information about the version of VCS running on the system.

```
# hastart -version
```

The command retrieves information about the engine version, the join version, the build date, and the PSTAMP.

```
# hastart -v
```

The command retrieves information about the engine version.

## Administering resource types

### Adding, deleting, and modifying resource types

After creating a resource type, use the command `haattr` to add its attributes. By default, resource type information is stored in the types.cf configuration file.

**To add a resource type**

```
# hatype -add resource_type
```

**To delete a resource type**

```
# hatype -delete resource_type
```

You must delete all resources of the type before deleting the resource type.

**To add or modify resource types in main.cf without shutting down VCS**

```
# hatype -modify resource_type SourceFile "./resource_type.cf"
```

The information regarding `resource_type` is stored in the file `config/resource_type.cf`, and an include line for `resource_type.cf` is added to the `main.cf` file. Make sure that the path to the `SourceFile` exists on all nodes before you run this command.

**To set the value of static resource type attributes**

```
# hatype - modify .
```
Overriding resource type static attributes

You can override some resource type static attributes and assign them resource-specific values. When a static attribute is overridden and the configuration is saved, the main.cf file includes a line in the resource definition for the static attribute and its overridden value.

To override a type's static attribute

```
# hares -override resource static_attribute
```

To restore default settings to a type's static attribute

```
# hares -undo_override resource static_attribute
```

Using the -wait option in scripts

The -wait option is for use in scripts using VCS commands to change attribute values. The option blocks the VCS command until the value of the specified attribute is changed or until the timeout, if specified, expires. Specify the timeout in seconds.

The option can be used only with changes to scalar attributes. The -wait option is supported with the following commands:

- **haclus**
  ```
  haclus -wait attribute value [-clus cluster] [-time timeout]
  
  Use the -clus option in a global cluster environment.
  ```

- **hagrp**
  ```
  hagrp -wait group attribute value [-clus cluster] [-sys system] [-time timeout]
  
  Use the -sys option when the scope of the attribute is local.
  Use the -clus option in a global cluster environment.
  ```

- **hares**
  ```
  hares -wait resource attribute value [-clus cluster] [-sys system] [-time timeout]
  
  Use the -sys option when the scope of the attribute is local.
  Use the -clus option in a global cluster environment.
  ```

- **hasys**
  ```
  hasys -wait system attribute value [-clus cluster] [-time timeout]
  
  Use the -clus option in a global cluster environment.
  ```
Administering simulated clusters from the command line

VCS Simulator is a tool to assist you in building and simulating cluster configurations. With VCS Simulator you can predict service group behavior during cluster or system faults, view state transitions, and designate and fine-tune various configuration parameters. This tool is especially useful when evaluating complex, multi-node configurations. It is convenient in that you can design a specific configuration without test clusters or changes to existing configurations.

You can also fine-tune values for attributes governing the rules of failover, such as Load and Capacity in a simulated environment. VCS Simulator enables you to simulate various configurations and provides the information you need to make the right choices. It also enables simulating global clusters.

See "Predicting VCS behavior using VCS Simulator" on page 457.
Administering the cluster from the command line

Administering simulated clusters from the command line
Configuring resources and applications in VCS

- About configuring resources and applications
- Configuring shared storage
- Configuring network resources
- Configuring file shares
- Configuring print shares
- Configuring Microsoft virtual machines
- Configuring IIS sites
- Configuring services
- Configuring processes
- Configuring a Microsoft Message Queuing (MSMQ) service group
- Configuring infrastructure and support agents
- Configuring applications using the Application Configuration Wizard
About configuring resources and applications

VCS monitors resources using agents. VCS detects the state of an application by continuously monitoring resources used by an application. If all resources required by the application are available, VCS declares the application as available.

Refer to the *Veritas Cluster Server Bundled Agents Reference Guide* for a description of the agents provided by VCS.

VCS provides configuration wizards to configure commonly-used resources. You can also use Cluster Manager (Java console), Cluster Management Console (Single Cluster Mode) also referred to as Web console, or the command line to configure resources.

**Note:** When modifying agent attributes from the Cluster Manager (Java console) and Cluster Management Console, use a single slash (\) to denote path names. When manually editing the configuration file main.cf directly, use double slashes (\\).

Configuring resources and applications in VCS involves the following tasks:

- Creating a service group comprising all resources required for the application and then configuring the resources.
  For example, to configure a database in VCS, you must configure resources for the database and for the underlying shared storage and network. Configuring a resource involves defining values for its attributes. The resources must be logically grouped in a service group. When a resource faults, the entire service group fails over to another node.

- Assigning dependencies between resources.
  For example, a MountV resource depends on a VMDg resource. Similarly, an IP resource depends on a NIC resource.

- Bringing the service group online.
Windows Server 2008 considerations

The following items apply if your setup involves Windows Server 2008 systems:

- **User Access Control (UAC)**
  On Windows Server 2008, if User Access Control (UAC) is enabled and configured, non-default administrators cannot run VCS commands from the command prompt. All VCS commands must be run from the command prompt in the *Run as administrator* mode. To launch the command prompt in the Run as administrator mode, right-click the command prompt shortcut from the Windows Start menu and click *Run as administrator* from the context menu.
  See the Microsoft documentation for more information on UAC.

- **Windows Firewall**
  If you have configured the Windows firewall on Windows Server 2008, ensure that the firewall settings allow access to the services or ports used by SFW HA.
  Refer to the Appendix in the *Veritas Storage Foundation Installation and Upgrade Guide* for a detailed list of SFW HA services and ports used.

- **Windows Server 2008 Server Core**
  If you wish to configure VCS resources and service groups on Windows Server 2008 Server Core systems, you must manually add the required resources and configure the service groups. You can perform the steps either directly on the Server Core machine using vcs commands from the command line, or remotely using the Cluster Manager (Java console).
  See “Administering the cluster from Cluster Manager (Java console)” on page 161.
  See “Administering the cluster from the command line” on page 259.

Before configuring resources and service groups, review the resource types and the attribute definitions described in the *Veritas Cluster Server Bundled Agents Reference Guide.*
Configuring shared storage

- If your configuration uses shared disks and volumes managed using Windows Logical Disk Manager, use the DiskReservation and Mount agents. See “Managing shared storage using Windows Logical Disk Manager” on page 309.

- If your configuration uses shared volumes or Logical Unit Numbers (LUNs) managed in a Network Appliance storage environment, use the NetAppSnapDrive and NetAppFiler agents. See “Managing storage in a Network Appliance storage environment” on page 313.

- If your configuration uses shared disks and volumes managed using Veritas Storage Foundation for Windows (SFW), use the VMDg and MountV agents. See “Managing shared storage using SFW” on page 315.

Before configuring shared storage, review the resource type and the attribute definitions of these agents in the Veritas Cluster Server Bundled Agents Reference Guide.
Managing shared storage using Windows Logical Disk Manager

Before configuring shared storage, review the resource type and the attribute definitions of the Disk Reservation and the Mount agents, described in the Veritas Cluster Server Bundled Agents Reference Guide.

About LDM support

The following restrictions apply in this release:

■ Disk Reservation and Mount agents are supported on VCS for Windows only. These agents are not supported in an SFW storage environment.
■ LDM support is available on Windows Server 2003 only.
■ For using LDM, your storage devices must be configured to use SCSI-2 disk reservations. SCSI-3 is not supported.
■ LDM support is not applicable for Disaster Recovery configurations. Currently only HA configurations are supported.

Prerequisites

■ Verify that the disk signature is the same on all systems sharing the disk. See “Reserving disks” on page 310.
■ Install software drivers for the disk controller device identically on each system in the cluster. Verify that these driver services run successfully on all systems.
■ Disable the option Reset SCSI Bus at IC Initialization from the SCSI Select utility.
■ If using the agents in a Fibre Channel (FC) setup, enable target resets for the adapters.
■ Verify that the device path to the disk is recognized by each system sharing the disk. See “Verifying disks are visible from Disk Management” on page 311.
■ Disable the write cache on the internal SCSI RAID controller.
■ For each system, unassign the drive letter for the disk device path configured for mounting. See “Unassigning a drive letter” on page 311.
Reserving disks
Complete the following steps for reserving disks.

To reserve the disks
1. To display all the disks, type the following on the command line:
   
   ```
   C:\>havol -scsitest /l
   ```
   
   You will see a table that lists all the disks that are visible from the current system. Make a note of the disk numbers (Disk# column in the table). You will need it in the next step.

2. To reserve a disk, type the following on the command line:
   
   ```
   C:\>havol -scsitest /RES:<disk #>
   ```
   
   For example, to reserve disk 4, type:
   
   ```
   C:\>havol -scsitest /RES:4
   ```
   
   Make a note of the disk number and the corresponding signature. You will require these details to identify and reserve the disks while configuring the Mount and DiskRes resources in a service group.

   For more details on the havol utility, see “The havol utility” on page 720.

Creating volumes
Perform the following steps to create volumes:

To create volumes
1. Use the Windows Disk Management tool to verify that the disks are visible on the cluster nodes, and then create volumes on the reserved disks.

2. After creating the required volumes on a node, release the reserved disks on that node.
   
   See “Releasing disks” on page 311.

3. Rescan the disks on all the remaining nodes in the cluster.
   
   Refer to Microsoft Windows documentation for more information about the Disk Management tool.

Mounting volumes
Use the Windows Disk Management tool to mount the volumes that you created earlier. After mounting the volumes on a cluster node, run the CHKDSK command and verify that there are no errors on the mounted volumes.

Make a note of the drive letters that you assign to the mounted volumes. Use the same drive letters while mounting these volumes on the remaining cluster nodes.
Refer to Microsoft Windows documentation for more information about the CHKDSK command and the Disk Management tool.

Verifying disks are visible from Disk Management

Complete the following steps:

**To verify that the disks are visible from a cluster node**

1. Log in as Administrator.
2. Open Disk Management. Type the following on the command prompt: `C:\> diskmgmt.msc`
3. Verify that the shared disks are visible in the right-pane.

Unassigning a drive letter

Complete these steps to unassign the drive letters from a node.

**To unassign a drive letter**

1. Log in as Administrator.
2. Open Disk Management. Type the following at the command prompt: `C:\> diskmgmt.msc`
3. Right-click the partition or logical drive and click **Change Drive Letter and Path**.
4. In the **Change Drive Letter and Paths** dialog box, click the drive letter and click **Remove**.

**Note:** You must run Disk Management on all systems each time you add a shared disk. This ensures each disk has a valid signature written to it, and that the device paths and symbolic links are updated.

Releasing disks

While installing an application on multiple nodes, you must first unassign drive letters and release the disks from one node, and then reserve the disks, mount the volumes using the same drive letters and then install the application on the failover node.

Complete the following steps to release reserved disks.
To release disks

1. To display all the disks, type the following on the command line:
   
   ```
   C:\>havol -scsitest /l
   ```
   
   You will see a table that lists all the disks that are visible from the current system. Make a note of the disk numbers (Disk# column in the table). You will need it in the next step.

2. To release a reserved disk, type the following on the command line:
   
   ```
   C:\>havol -scsitest /REL:<disk #>
   ```

   For example, to release disk 4, type:
   
   ```
   C:\>havol -scsitest /REL:4
   ```

**Configuration tasks**

Complete the following steps to manually configure Mount and DiskRes resources in the cluster.

1. In your service group, create resources of type DiskReservation and Mount. See “Adding a resource” on page 223 for instructions.

2. Configure the following required attributes for these resources:
   
   **DiskReservation Resource**
   
   - **Signatures**: An array specifying the signature of each SCSI disk. VCS provides the havol utility to retrieve disk signatures. See “The havol utility” on page 720 for instructions.

   **Mount Resource**
   
   - **MountPath**: The drive letter or path to an empty NTFS folder that will be assigned to the volume being mounted.
   - **PartitionNo**: The partition on the disk configured for mounting.
   - **Signature**: A system-specified disk identifier. VCS provides a utility, “havol,” to retrieve the disk signature. See “The havol utility” on page 720 for instructions.

3. Link the Mount and DiskReservation resources such that the Mount resource depends on the DiskReservation resource. See “Linking resources” on page 236 for instructions.

4. Configure other resources in the service group, if required.

5. Bring the Mount resource online.
Managing storage in a Network Appliance storage environment

Network Appliance manages data by creating volumes on physical disks. These volumes can further be divided into Logical Unit Numbers (LUNs). The LUNs are accessible from the cluster nodes, provided the nodes have Microsoft iSCSI Initiator and Network Appliance SnapDrive installed. If you plan to use Fibre Channel (FC) for connecting the LUNs, ensure that you install the NetApp FCP Attach Kit on all the cluster nodes.

Perform the following tasks to create the required LUNs on the Network Appliance Filer and to make them accessible from cluster nodes:

■ Create volumes on the Network Appliance Filer.
■ Share the volumes.
■ Create LUNs on the shared volumes.

Refer to Network Appliance documentation for instructions on performing these tasks.

Configuring Microsoft iSCSI Initiator

The Microsoft iSCSI initiator enables communication between Windows systems and Network Appliance Filers. The initiator uses the iSCSI protocol to present the filer volume as a local block device to the system.

To configure Microsoft iSCSI initiator

1. Make sure the Microsoft iSCSI Initiator software version 2.0 is installed on all cluster nodes. Refer to Microsoft documentation for further information.
2. Start the Microsoft iSCSI initiator. Double-click the Microsoft iSCSI Initiator icon from the desktop.
3. Click the Target Portals tab, if not already selected.
4. Click Add.
5. In the Add Target Portals dialog box, specify the IP address or the DNS name for the Network Appliance Filer and click OK.
6. Click the Available Targets tab and click Log On.
7. In the Log On to Target dialog box, verify the target portal name and select the Automatically restore this connection when the system reboots check box.
8. Click OK.
9. Click the Persistent Target tab to verify that the newly added target portal is listed under the Select a target box.
Connecting virtual disks to the cluster node

Once the required virtual disks are created on the Network Appliance Filer, they must be connected (if not connected already) to the cluster nodes using Network Appliance SnapDrive.

To connect virtual disks to the cluster node
1. Start the Computer Management MMC on the cluster node where you want to connect the LUN. Click Start > All Programs > Administrative Tools > Computer Management.
2. From the left pane, expand Storage and double-click SnapDrive.
3. Double-click Disks to see the LUNs that are connected to the node.
4. Right-click the LUN you want to connect and then click Connect Disk.
5. In the Connect Disk alert box, click OK.

Disconnecting virtual disks from the cluster nodes

Steps to disconnect the virtual disks from a cluster node.

To disconnect virtual disks
1. Start the Computer Management MMC on the cluster node where you want to disconnect the LUN. Click Start > All Programs > Administrative Tools > Computer Management.
2. From the left pane, expand Storage and double-click SnapDrive.
3. Double-click Disks to see the LUNs that are connected to the node.
4. Right-click the LUN you want to disconnect and then click Disconnect Disk....
5. In the Disconnect Disk alert box, click OK.
Managing shared storage using SFW

Before configuring shared storage, review the resource type and the attribute definitions of the VMDg and the MountV agents in the *Veritas Cluster Server Bundled Agents Reference Guide*.

---

**Note:** If your storage devices are SCSI-3 compliant, and you wish to use SCSI-3 Persistent Group Reservations (PGR), you must enable SCSI-3 support using the Veritas Enterprise Administrator (*VEA - Control Panel - System Settings*). See the *Veritas Storage Foundation Administrator’s Guide* for more information.

---

**Using SFW with VCS**

The following advanced features of SFW require special consideration when used in a VCS environment:

- **Deporting Disk Groups**
  SFW does not allow disk groups configured as VCS resources to be deported. They must be brought online or taken offline using VCS.

- **Dynamic Group Split and Join (DGSJ)**
  SFW does not allow splitting a disk group configured as a VCS resource if the split operation causes a volume configured as a VCS resource to be part of the target group.
  SFW does not allow a disk group configured as a VCS resource to be the source disk group in a join operation.

- **Deleting Volumes**
  SFW does not allow deleting volumes configured as VCS resources.

- **Volume Snap Back**
  If a volume formed as a result of a Prepare and Snap Shot operation, is configured as a VCS resource, SFW does not allow Snap Back operations on the volume.

See the Veritas Storage Foundation documentation for more information about these operations.

---

**Prerequisites**

- Verify that SFW HA or VCS for Windows is installed on all cluster systems.
- If you have configured Windows Firewall, add port 2148 to the Firewall Exceptions list.
For a detailed list of services and ports used by SFW HA, refer to the *Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide*.

- Configure the clustered disk group using Storage Foundation. Verify the disk group contains shared disks only.
- Disable the option **Reset SCSI Bus at IC Initialization** from the SCSI Select utility.
- Create a separate clustered disk group for each application to be clustered. Do not create a clustered disk group for more than one application. Configure all volumes or LUNs to be part of the VCS configuration and of the same service group.
- Assign a unique disk group name to each clustered disk group within a cluster.
- Ensure that the device path to the shared disk group or LUNs is recognized by all systems sharing the disk.

**Configuration tasks**

- In your service group, create the following resources:
  - For SFW HA, create resources of type VMDg and MountV.
  - For VCS for Windows, create resources of type NetAppFiler and NetAppSnapDrive.
  
  See “Adding a resource” on page 223 for instructions.

- Configure the following required attributes for these resources:
  
  **VMDg Resource**
  - **DiskGroupName**: The name of the cluster disk group. Retrieve the name by running the command `vxdg list`, or by using the VMGetDrive utility.
    
    See “The vmgetdrive utility” on page 724 for more information.

  **MountV Resource**
  - **MountPath**: The drive letter or path to an empty NTFS folder that will be assigned to the volume being mounted.
  - **VolumeName**: The name of the volume to be mounted. For example, the name could be Raid1, Stripe2, Volume01, etc. Use the VMGetDrive utility to retrieve the volume name.
    
    See “The havol utility” on page 720 for instructions.

  **NetAppFiler resource**
  - VMDGResName: The name of the Volume Manager Diskgroup (VMDg) resource on which the MountV resource depends.
Configuring shared storage

- FilerName: DNS-resolvable name or IP address of the locally attached filer.
- StorageIP: The private storage IP address of the filer.

NetAppSnapDrive resource
- FilerResName: Name of the VCS NetAppFiler-type resource in the service group.
- VolumeName: Name of the volume containing the virtual disk. Define the volume name in the same case as on the filer.
- ShareName: Name of the CIFS share containing the virtual disk.
- LUN: Name of the LUN on the filer that is presented to the host for mounting. Define the LUN name in the same case as on the filer.
- MountPath: Drive letter to be assigned to the virtual disk.
- Initiator: Name of the iSCSI or FC initiator that the host uses to connect to the virtual disks on the filer. You can retrieve this from the Disk Management console.

- Link the resources as follows:
  - For SFW HA, link MountV and VMDg resources such that the MountV resource depends on the VMDg resource.
  - For VCS for Windows, link NetAppSnapDrive and NetAppFiler resources such that the NetAppSnapDrive resource depends on the NetAppFiler resource.

See “Linking resources” on page 236 for instructions.

- Configure other resources in the service group, if required.
- Bring the MountV or the NetAppSnapDrive resource online.
Configuring network resources

This section provides an overview of the steps involved in configuring network resources in a VCS cluster.

- If each system in your cluster uses a single adapter for the public network, use the NIC and IP agents.
- If your cluster systems use multiple adapters for the public network, use the IPMultiNICPlus agent.
- If your cluster systems use virtual computer names, use the Lanman agent.

Configuring IP addresses in single-adapter systems

Before configuring the network resources, review the resource type and the attribute definitions of the NIC and IP agents, described in the Veritas Cluster Server Bundled Agents Reference Guide.

Prerequisites

- Ensure that the NIC has the correct administrative IP address and subnet mask.
- If the NICs have built-in failover support, disable it. Refer to the documentation provided by the NIC vendor.
- Do not configure IP addresses added from the Control Panel.
- Verify that the virtual IP address to be assigned is unique and does not exist in the network.
- Disable DHCP on the NIC.

Disabling DHCP

To disable DHCP

1. Open the Network Connections Control Panel.
2. Right-click the network connection and click Properties.
3. In the Properties dialog box for the respective local area connection, select the General tab, if not already selected.
4. Select Internet Protocol (TCP/IP) and click Properties.
5. Verify that the Obtain an IP address automatically option is not selected.
6. Specify values for IP address, Subnet mask, and Default Gateway, if not already specified.
7  Click **OK** and close the Control Panel.

**Configuration tasks**

1. In your service group, create resources of type NIC and IP. See “Adding a resource” on page 223 for instructions.

2. Configure the following required attributes for these resources:
   - **NIC Resource**
     - **MACAddress**: The physical address of the NIC to be monitored. You can retrieve the physical addresses of NICs using the command `ipconfig -all`. Note that this attribute is always local.
     - **UseConnectionStatus**: A flag that defines whether the NIC maintains its connection status.
   - **IP Resource**
     - **Address**: The unique virtual IP address to be assigned to the NIC.
     - **MACAddress**: The physical address of the NIC to which the virtual IP address is assigned. Note that this attribute is always local.
     - **SubNetMask**: The subnet mask associated with the IP address.
     Ensure that the value of the attribute UseConnectionStatus is correct. This value is set to True by default, and indicates that all NICs maintain their connection status. If UseConnectionStatus is set to False, ensure that the NIC has an IP address assigned and that at least one host is listed in the attribute PingHostList.

3. Link the IP and NIC resources such that the IP resource depends on the NIC resource. See “Linking resources” on page 236 for instructions.

4. Configure other resources in the service group, if required.

5. Bring the IP resource online.

**Configuring IP addresses in multiple-adapter systems**

Before configuring the agent, review the resource type and the attribute definitions of the agent, described in the *Veritas Cluster Server Bundled Agents Reference Guide*.

**Prerequisites**

- Ensure that the NIC has the correct administrative IP address and subnet mask.
- Disable DHCP.
Configuring resources and applications in VCS

Configuring network resources

See “Configuring IP addresses in single-adapter systems” on page 318 for instructions.

- If the NICs have built-in failover support, disable it. Refer to the documentation provided by the NIC vendor.
- Do not configure IP addresses added from the Control Panel.
- Verify that the virtual IP address to be assigned is unique and does not exist in the network.
- Verify that NICs on a single system are connected to the same network segment.

Configuration tasks

1. In your service group, create a resource of type IPMultiNICPlus. See “Adding a resource” on page 223 for instructions.

2. Configure the following required attributes for the resource:
   - AdapterList: A list of MAC addresses (physical addresses) of NICs that form the IPMultiNicPlus resource.
   - Address: The unique virtual IP address to be assigned to the active NIC.
   - AdminIPAddr: Unique administrative IP address assigned to the active NIC in the AdapterList attribute. Note that this attribute is always local. If this attribute is configured incorrectly, the system will not be accessible in the network until you bring the IPMultiNicPlus resource online on the system.
   - AdminSubnetMask: The subnet mask associated with the administrative IP address. Note that this attribute is always local.
   - SubNetMask: The subnet mask associated with the virtual IP address.

3. Configure other resources in the service group, if required.

4. Bring the IPMultiNICPlus resource, and other resources in the service group, online.

Configuring virtual computer names

Before configuring the agent, review the resource type and the attribute definitions of the Lanman agent, described in the Veritas Cluster Server Bundled Agents Reference Guide.

Prerequisites

- Remove static entries mapping the virtual name to the IP address from your WINS server.
If using the agent to bind multiple IP addresses to a virtual computer name, make sure the IP addresses belong to different subnets.

Make sure the VCS Helper domain user account has "Add workstations to domain" privilege enabled in the Active Directory.

DNS scavenging affects virtual servers configured in VCS because the Lanman agent uses DDNS to map virtual names with IP addresses. If you use scavenging, then you must set the DNSRefreshInterval attribute for the Lanman agent. This will enable the Lanman agent to refresh the resource records on the DNS servers. See the Lanman agent description in the Veritas Cluster Bundled Agents Reference Guide.

**Configuration tasks**

1. In your service group, create resources of type NIC and IP. See “Configuring IP addresses in single-adapter systems” on page 318 for instructions.

2. Create a resource of type Lanman.

3. Configure the following required attributes for the resource:
   - VirtualName: The virtual computer name to be assigned to the server.
   - IPResName: The name of the IP resource on which the Lanman resource depends. The IPResName attribute is not required if you have the MultiNet attribute set to 1.

4. Link the IP and NIC resources such that
   - the IP resource depends on the NIC resource, and
   - the Lanman resource depends on the IP resource.
   See “Linking resources” on page 236 for instructions.

5. Configure other resources in the service group, if required.

6. Bring the Lanman resource, and other resources in the service group, online.
Configuring file shares

This section describes how to configure file shares in VCS. There are several ways to configure file shares, including the configuration wizard, Cluster Manager (Java console), and the command line. This section provides instructions on how to use the configuration wizard to configure file shares.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using vcs commands from the command line, or remotely using the Cluster Manager (Java console).

See "Administering the cluster from Cluster Manager (Java console)" on page 161.

See "Administering the cluster from the command line" on page 259.

Before configuring file shares manually, note the following:

- To configure a shared directory, use the FileShare agent.
- To configure multiple directories, use the CompositeFileShare agent.
- If User Access Control (UAC) is enabled on Windows Server 2008 systems, you must launch the command prompt in the Run as administrator mode and then run the VCS commands.
- Before configuring the service group, review the resource types and the attribute definitions of the FileShare agents described in the Veritas Cluster Server Bundled Agents Reference Guide.

Before configuring file shares

Note the following prerequisites before you configure file shares in VCS:

- Verify that you have local administrator privileges on the system where you run the wizard.
- If you have configured a firewall, add the following to the firewall exceptions list:
  - Port 14150 or the VCS Command Server service, %vcs_home%\bin\CmdServer.exe
    Here, %vcs_home% is the installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.
  - Port 14141
    For a detailed list of services and ports used by VCS, refer to the product installation and upgrade guide.
- Verify that the VCS high availability engine (HAD) is running on the system where you run the wizard.
Configuring file shares

- Verify that the directories to be shared reside on shared drives.
- If your storage is SCSI-3 compliant and you wish to use SCSI-3 persistent reservations, enable SCSI-3 support using Veritas Enterprise Administrator (VEA). This is applicable for SFW HA only.
- Mount the drives or LUNs containing the shared directories from the system from which you run the wizard. Unmount the drives or LUNs from other systems in the cluster.
  See “Managing shared storage using Windows Logical Disk Manager” on page 309 for more information.
  See for “Managing storage in a Network Appliance storage environment” on page 313 more information.
  See for “Managing shared storage using SFW” on page 315 more information.
- Verify that Veritas Command Server service is running on all systems in the cluster.
- Verify that you have the following information ready; the wizard will prompt you for these details:
  - A unique virtual computer name to be assigned to the file share server. This is the name by which clients access the server. The virtual name must not exceed 15 characters. If you specify a virtual computer name in lowercase letters, the name is converted to uppercase. For example, the name VCSServer is converted to VCSSERVER.
  - A unique virtual IP address to be assigned to the file share server. This is the IP address that the clients can use to access the file share.

  **Note:** Windows Server 2008 does not support accessing file shares using the virtual IP address.

- The list of directories to be shared.
The wizard enables you to add existing shares to the VCS configuration. However, you cannot add special shares (shares created by the operating system for administrative and system use). For example, you cannot add the shares ADMIN$, print$, IPC$, and DriveLetter$ to the VCS configuration.

Creating a file share service group using the configuration wizard

The File Share Configuration Wizard enables you to create and modify file share service groups, making file shares highly available in a VCS cluster.
To create a file share using the File Share Configuration Wizard

2. Review the information in the Welcome panel and click Next.

3. On the Wizard Options panel click Create service group and then click Next.

4. On the Service Group Configuration panel, specify the service group details and then click Next. The wizard then starts validating your configuration. Various messages indicate the validation status.

Service Group Name: Type a name for the file share service group.
On the FileShare Configuration panel, specify the configuration information for the FileShare resources to be created and then click **Next**. The wizard begins validating your configuration. Various messages indicate the validation status.

5. On the FileShare Configuration panel, specify the configuration information for the FileShare resources to be created and then click **Next**. The wizard begins validating your configuration. Various messages indicate the validation status.

**Available Cluster Systems**

Select the systems on which to configure the service group and click the right arrow to move the systems to the service group's system list.

To remove a system from the service group's system list, click the system in the Systems in Priority Order box and click the left arrow.

To change a system's priority in the service group's system list, click the system from the Systems in Priority Order and click the up and down arrows.

System priority defines the order in which service groups are failed over to systems. The system at the top of the list has the highest priority while the system at the bottom of the list has the lowest priority.

**Virtual Computer Name**

Type a unique virtual computer name by which the server will be known to clients. The virtual name must not exceed 16 characters.
Configuring file shares

List Shares

Click **List Shares** to view the existing shares on the shared storage, then select a share and click **Add**. You cannot add special shares (shares created by the operating system for administrative and system use).

Path

Click the field and either type the path of the directory to be shared or click the ellipsis button (…) to browse for a directory.

The selected directories must meet the following conditions:

- The selected drive, the mount path, and the file path must not exist in the VCS configuration.
- The directories to be shared must reside on shared, non-system drives.

The wizard validates the selected directory and displays an error message if the directory does not meet any of the conditions.

Share Name

If a selected directory is already shared, the Share Name column lists the names by which it is shared. You can select a listed share name to make an existing share highly available. You can also create a new share for the same directory by typing a new share name.

Remove

To remove a file share from the configuration, click to select the file share, and then click **Remove**.

Configure NetApp SnapMirror Resource(s)

This is applicable in case of VCS for Windows only. Check the **Configure NetApp SnapMirror Resource(s)** check box if you wish to set up a disaster recovery configuration. The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration.

Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site.
6 On the Share Permissions panel, select the file share, specify users for the file shares and assign permissions to them, and then click **Next**.

**Select the FileShare**  
From the drop-down list, select the file share with which to associate user permissions, or select the default **All FileShares** to set the same permissions for all file shares.

**Select the Permission**  
From the drop-down list, select the permission to be associated with the user.

**Select the User**  
Click the ellipsis button (…), select a user, and click **OK**.

**Add**  
Click **Add** to add the specified user to the Selected Users list. By default, all selected users are given **READ_ACCESS** permission.

**Selected Users**  
Displays a list of selected users and the file share permissions. You can configure a maximum of 50 users for each file share. To configure more users, create a user group.  
To change the file share permission associated with a user, click a user name in the Selected Users list and then select the desired permission from the Select the Permission drop-down list.  
To deny file share access to a user, click the user name in the Selected Users list and click **Remove**.
7 On the Share Properties panel, set the share properties for the file shares and then click **Next**.

Select the FileShare From the drop-down list select a file share whose properties you wish to set.

Enable access-based enumeration for this file share Check the **Enable access-based enumeration** check box to enable the Windows access-based enumeration feature on the selected file share.

User Limit Specify the number of users that are allowed access to the selected file share.

Choose from the following options:

- **Maximum allowed users**: Select this option to allow access to the maximum numbers of users allowed on Windows.

- **Allow this number of users**: Select this option and then type the number of users that you wish to grant access to the selected file share. If you type zero or a value greater than what Windows supports, access is granted to the maximum users allowed on Windows.
Enable cache: Check the **Enable cache** check box to enable local caching of the contents of the selected file share. Then, specify how the contents of the file share are available to users for offline access. In the drop down list select from the following caching options:

- **Manual caching of files and programs**: Only the files and programs specified by the user are available offline. This sets the FileShare resource attribute ClientCacheType to **MANUAL**.
- **Automatic caching of programs**: All the files and programs that the users access from the file share are available offline. This sets the FileShare resource attribute ClientCacheType to **DOCS**.
- **Optimized automatic caching of files and programs**: All files and programs, including executables, are cached locally. The next time the user accesses the executable files, they are launched from the local cache. This sets the FileShare resource attribute ClientCacheType to **PROGRAMS**.

Hide share: Check the **Hide Share** check box to make the new share a hidden share.

Share all subfolder: Check the **Share all subfolders** check box to share the subdirectories.

Hide child shares: Check the **Hide child shares** check box to hide the shared subdirectories.

Apply these settings to: To apply the specified share properties to multiple file shares simultaneously, do the following:

1. Click the ellipsis button (...).
2. On the Copy Share Properties dialog box, select the file shares from the Available Shares list and click the right arrow to move them to the Selected Shares list. Note that only those file shares that are not already shared are available for selection.
3. Click **OK**.

Note: This option is not visible if you are configuring only one share in the service group.

---

**8** This is applicable in case of VCS for Windows only.

On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click **Next**.
If you are configuring Multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

9. On the Network Configuration panel, specify information related to your network and then click Next.

### Virtual IP Address
Type a unique virtual IP address for the virtual server.

### Subnet Mask
Type the subnet to which the virtual IP belongs.

### Adapter Display Name
For each system in the cluster, select the public network adapter name. This field displays the TCP/IP enabled adapters on a system, including the private network adapters, if applicable. To view the adapters associated with a system, click the Adapter Display Name field and click the arrow. Verify that you select the adapters assigned to the public network, not the private.
Advanced Settings

Click Advanced Settings to specify additional details for the Lanman resource. On the Lanman Advanced Configuration dialog box, complete the following:

1. Check Active Directory Update required check box to enable the Lanman resource to update the Active Directory with the virtual name. This sets the Lanman agent attributes ADUpdateRequired and ADCriticalForOnline to true.

2. In the Organizational Unit field, type the distinguished name of the Organizational Unit for the virtual server in the format
   \texttt{CN=containername,DC=domainname,DC=com}.
   To browse for an OU, click the ellipsis (...) button and search for the OU using the Windows Find Organization Units dialog box.
   By default, the Lanman resource adds the virtual server to the default container “Computers.”

3. Click OK.
   The user account for VCS Helper service must have adequate privileges on the specified container to create and update computer accounts.

10. On the Service Group Summary panel, review the service group configuration and click Next. A message appears informing you that the wizard will run commands to modify the service group configuration. Click Yes. The wizard starts
running commands to create the service group. Various messages indicate the status of these commands.

In the completion dialog box, check **Bring the service group online** check box if you want to bring the service group online on the local system, and then click **Finish**.
Modifying a file share service group using the wizard

The File Share Configuration Wizard enables you to modify a file share service group.

- If the file share service group is online, you must run the wizard from a system on which the service group is online. You can then use the wizard to add resources to and remove them from the configuration. You cannot change attributes of resource that are online.

- To change the resource attributes, you must take the service group offline. However, the MountV and VMDg (in case of SFW HA), Mount and DiskRes (in case of Windows LDM) and NetAppSnapDrive and NetAppFiler (in case of VCS for Windows) resources for the service group should be online on the node where you run the wizard and offline on all other nodes.

- If you are running the wizard to remove a node from the service group’s system list, do not run the wizard on the node being removed.

- If the service group contains resources that were not part of the default service group configuration, then modifying the service group may change those resources. You may then have to manually restore the settings of those resources later.

To modify a file share service group using the File Share Configuration Wizard

1. Start the File Share Configuration Wizard on a system on which the file share service group is online. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > File Share Configuration Wizard)
2. Review the information in the Welcome panel and click Next.
3. On the Wizard Options panel, click Modify service group, select the service group to be modified, and click Next.
4. Follow the wizard instructions described between step 4 through step 11 in the file share service group creation procedure. See “Creating a file share service group using the configuration wizard” on page 323.
Deleting a file share service group using the wizard

This section describes steps to delete a file share service group using the configuration wizard.

To delete a file share service group using the File Share Configuration Wizard

1. Start the File Share Configuration Wizard on a system configured to host the file share service group. (*Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > File Share Configuration Wizard*)

2. Review the information in the Welcome panel and click **Next**.

3. On the Wizard Options panel, click **Delete service group**, select the service group to be deleted, and click **Next**.

4. On the Service Group Summary panel, click **Next**. A message appears informing you that the wizard will run commands to delete the service group. Click **Yes** to delete the service group.

5. Click **Finish**.
Configuring file share with multiple subdirectories

Use the VCS CompositeFileShare agent to configure file share with multiple subdirectories. Before configuring a file share service group, review the resource types and the attribute definitions of the CompositeFileShare agent, described in the *Veritas Cluster Server Bundled Agents Reference Guide*.

VCS provides configuration wizards to configure commonly-used resources. You can also use Cluster Manager (Java console), Cluster Management Console (Single Cluster Mode) also referred to as Web console, or the command line to configure resources.

See "Administering the cluster from Cluster Manager (Java console)" on page 161.
See "Administering the cluster from the command line" on page 259.

Before configuring multiple shares

Note the following prerequisites before configuring file share using the CompositeFileShare agent:

- Verify that the directories to be shared are on shared disks or LUNs.
- Do not use local system accounts for share users. Use domain-level accounts and users only.

**Note:** Sharing a directory with a large number of subdirectories and enabling the ShareSubdirectories flag could cause increased failover time and high CPU and memory utilization.

**Configuration tasks**

1. Configure your shared storage.  
   See “Configuring shared storage” on page 308.

2. Configure the NIC and IP resources.  
   See “Configuring IP addresses in single-adapter systems” on page 318.

3. Create a resource of type CompositeFileShare.  
   See “Adding a resource” on page 223 for instructions.

4. Configure the following required attributes for the CompositeFileShare resource:
   - MountResName: The name of the MountV resource on which the Composite FileShare resource depends.
   - PathAndShareName: A list specifying the respective paths and share names of the directories to be shared. If the path of a shared directory
is \Documents, and the share name is UserDocs, the attribute is defined in the configuration file as PathandShareName is \\"Documents\" = "UserDocs".

To create a hidden share, set the HiddenShare attribute to 1. Do not append the share name with a $ (dollar) sign.

For more information on other attributes, refer to the *Veritas Cluster Server Bundled Agents Reference Guide*.

5 Configure a Lanman resource. Do not create other resources on which the Lanman agent depends.

See “Configuring virtual computer names” on page 320 for instructions.

6 Link resources to create the following dependencies:
   ■ CompositeFileShare resource depends on the MountV (in case of SFW HA) or NetAppSnapDrive (in case of VCS for Windows) resource.
   ■ Composite FileShare resources depends on the Lanman resource.
   ■ Lanman resource depends on IP resource, which in turn depends on the NIC resource.

See “Linking resources” on page 236 for instructions.

7 Configure other resources in the service group, if required.

8 Bring the Lanman resource, and other resources in the service group, online.
Configuring print shares

This section provides an overview of the steps involved in configuring a print share service group in a VCS cluster. A print share service group enables clients to share a network printer from a cluster.

VCS provides several ways to configure a print share service group, including the configuration wizard, Cluster Manager (Java console), and the command line. This section provides instructions on how to use the Print Share configuration wizard to configure print shares.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using the command line, or remotely using the Cluster Manager (Java console).

See “Administering the cluster from Cluster Manager (Java console)” on page 161.
See “Administering the cluster from the command line” on page 259.

Before configuring a print share service group, review the resource types and attribute definitions of the PrintShare agents, described in the Veritas Cluster Server Bundled Agents Reference Guide.

Upgrade considerations

The PrintSpool agent has been enhanced to meet scalability and performance requirements. The PrintSpool agent no longer depends on the RegRep agent for operation. The dependency between the PrintSpool and the RegRep resource in a print share service group has been eliminated.

This affects print share service groups configured in VCS versions 5.0.x or earlier. If you have configured a print share and you upgrade VCS, then the existing print share service group will fail to come online, after the upgrade.

After the upgrade is complete, you must run the Print Share Configuration Wizard to modify the print share service group. This will allow the wizard to make the required changes to the service group configuration.

**Note:** In case of an upgrade, do not add or remove any resources, or modify any other attributes in the print share service group for the first time you run the Print Share Configuration Wizard to modify the service group.

Before you modify the existing print share service group:

- Make sure that the VCS engine (HAD) is running on the cluster node.
Mount the drives or LUNs that contain the spooler and the registry replication diretories on the system on which you will run the wizard. Unmount the drives or LUNs from other systems in the cluster. See “Managing shared storage using Windows Logical Disk Manager” on page 309 for more information. See for "Managing storage in a Network Appliance storage environment" on page 313 more information. See for "Managing shared storage using SFW" on page 315 more information.

To modify the print share service group after an upgrade
1. Start the Print Share Configuration Wizard. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Print Share Configuration Wizard)
2. Read the information on the Welcome panel and click Next.
3. On the Wizard Options panel, click Modify service group, select your existing print share service group, and then click Next.
4. On the Service Group Configuration panel, click Next.
5. On the Configure Data Path panel, complete the following and then click Next.

   - Spooler Directory: Leave this field as it is. Do not make any changes to the spooler directory path.
   - Replication Directory: Type the path or click the ellipsis button (...)to browse for the directory. All changes related to the printer registry keys will be logged at this location. The selected directory must reside on a shared, non-system drive.

6. Click Next on the subsequent wizard panels and complete the wizard steps. You can now bring the printshare service group online.

Before configuring print shares

Note the following prerequisites before you configure print shares in VCS:

- Verify that you have local administrator privileges on the system where you run the wizard.
- If you have configured a firewall, add the following to the firewall exceptions list:
■ Port 14150 or the VCS Command Server service, %vcs_home%\bin\CmdServer.exe
   Here, %vcs_home% is the installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.

■ Port 14141
   For a detailed list of services and ports used by SFW HA, refer to the Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide.

■ Verify that the VCS high availability engine, HAD, is running on the system from which you run the wizard.

■ Verify that VCS Command Server service is running on all systems in the cluster.

■ Verify that the network printer has an IP address assigned.

■ Symantec recommends creating spooler and the replication directories on different disk partitions or volumes or LUNs.

■ Mount the drives or LUNs with the spooler and the replication directories from the system on which you run the wizard. Unmount the drives or LUNs from other systems in the cluster.
   See “Managing shared storage using Windows Logical Disk Manager” on page 309 for more information.
   See for "Managing storage in a Network Appliance storage environment" on page 313 more information.
   See for "Managing shared storage using SFW" on page 315 more information.

■ If your storage is SCSI-3 compliant and you wish to use SCSI-3 persistent reservations, enable SCSI-3 support using Veritas Enterprise Administrator (VEA). This is applicable for SFW HA only.

■ Verify that you have the following information ready. The wizard will prompt you for this information:
   ■ A unique virtual computer name to be assigned to the print share server. This is the name by which clients will access the server. The virtual name must not exceed 16 characters. If you specify a virtual computer name in lowercase letters, the name is converted to uppercase. For example, the name VCSServer is converted to VCSSERVER.
   ■ A unique virtual IP address to be assigned to the print share server.
   ■ The network printer’s IP address.
Creating a print share service group using the wizard

The Print Share Configuration wizard enables you to create and modify a print share service group in a VCS cluster. This section describes how to create a print share service group using the wizard.

You can also modify an existing print share service group using the wizard. See “Modifying a print share service group using the wizard” on page 350.

Creating a print share service group involves the following tasks:

- Create a new service group with a PrintSpool resource and bring it online. This also involves configuring the Lanman resource on which the PrintSpool resource depends.
- Add a network printer to the virtual computer created by the Lanman resource. Create a new TCP/IP port for the printer.
- Configure a PrintShare resource in your service group and bring it online.

To create a print share service group using the Print Share Configuration Wizard

1. Start the Print Share Configuration Wizard.
   
   Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Print Share Configuration Wizard.

2. Review the information in the Welcome panel and click Next.

3. On the Wizard Options panel, click Create service group and click Next.
4 On the Service Group Configuration panel, specify the service group details and click **Next**. The wizard then starts validating your configuration. Various messages indicate the validation status.

**Service Group Name**
Type a name for the print share service group.

**Available Cluster Systems**
Select the systems on which to configure the service group and click the right arrow to move the systems to the service group's system list.

To remove a system from the service group's system list, click the system in the Systems in Priority Order box and click the left arrow.

To change a system's priority in the service group's system list, click the system from the Systems in Priority Order and click the up and down arrows.

System priority defines the order in which service groups are failed over to systems. The system at the top of the list has the highest priority while the system at the bottom of the list has the lowest priority.
On the Virtual Server Configuration panel, specify information related to your network and then click **Next**.

**Virtual Server Name**
Type a unique virtual computer name by which the print share server will be known to clients. Note that the virtual name must not exceed 16 characters.

**Virtual IP Address**
Type a unique virtual IP address for the virtual server.

**Subnet Mask**
Type the subnet to which the virtual server belongs.

**Adapter Display Name**
Displays the TCP/IP enabled adapters on a system, including the private network adapters, if applicable. To view the adapters associated with a system, click the Adapter Display Name field and click the arrow. For each system in the cluster, select the public network adapter name. Verify that you select the adapters assigned to the public network, not the private.
Advanced Settings

Click Advanced Settings to specify additional details for the Lanman resource.

On the Lanman Advanced Configuration dialog box, complete the following:

1. Check Active Directory Update required check box to enable the Lanman resource to update the Active Directory with the virtual name. This sets the Lanman agent attributes ADUpdateRequired and ADCriticalForOnline to true.

2. In the Organizational Unit field, type the distinguished name of the Organizational Unit for the virtual server in the format
   \[ CN=containername,DC=domainname,DC=com \].
   To browse for an OU, click the ellipsis (...) button and search for the OU using the Windows Find Organization Units dialog box.
   By default, the Lanman resource adds the virtual server to the default container "Computers."

3. Click OK.
   The user account for VCS Helper service must have adequate privileges on the specified container to create and update computer accounts.
6 On the Configure Data Path panel, specify the directories for spool and registry replication, specify the other options on this panel and then click **Next**.

- **Spooler Directory**
  - Type the path or click the ellipsis button (…) to browse for the directory. All print commands will be spooled at this location.

- **Replication Directory**
  - Type the path or click the ellipsis button (…) to browse for the directory. All changes related to the printer registry keys will be logged at this location.
  
  The selected directories must fulfill the following conditions:

  - The selected drive, the mount path, and the file path must not exist in the VCS configuration.
  - The directories to be shared must reside on shared, non-system drives.
  
  Symantec recommends creating the directories for replication and spooling on different mounts.
345 Configuring resources and applications in VCS

Configuring print shares

This is applicable in case of VCS for Windows only.

On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click Next.

If you are configuring multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

Configure NetApp SnapMirror Resource(s)

This is applicable in case of VCS for Windows only.

Check the Configure NetApp SnapMirror Resource(s) check box if you wish to set up a disaster recovery configuration. The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration.

Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site.

7 This is applicable in case of VCS for Windows only.

On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click Next.

If you are configuring multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

8 On the Build Print Server panel, review the configuration and click Next. A message appears informing you that the wizard will run commands to modify the service group configuration. Click Yes. The wizard starts running commands to add the PrintSpool resource and the resources on which the
PrintSpool resource depends, including the Lanman and ServiceMonitor resources.

| Resources | Displays a list of configured resources. The wizard assigns unique names to resources. Change the names of resource, if required. To edit a resource name, select the resource name and either click it or press the F2 key. Edit the resource name and then press the Enter key to confirm the changes. To cancel editing a resource name, press the Esc key. |
| Attributes | Displays the attributes and their configured values, for a resource selected in the Resources list. |

9 Bring the PrintSpool resource online.

Proceed to the next step to add the network printer to the virtual computer created by the Lanman resource and to create a new TCP/IP port for the printer.

**To add the network printer to the virtual computer**

1 Launch the Add Printer wizard to add the network printer to the virtual computer. Before starting the Add Printer wizard, verify that the PrintSpool and Lanman resources are online in your configuration.

To launch the Add Printer wizard, return to the Print Share Configuration Wizard and click **Add Printer** on the Add Printer panel, or in Windows Explorer, search for the virtual computer, explore the virtual computer by
double-clicking its name and on the virtual computer’s Printers folder, double-click **Add Printer**.

2 In the Add Printer wizard, review the information in the Welcome panel and click **Next**.

3 Follow the wizard instructions to add the network printer to the virtual computer.
   In the Printer Sharing dialog box, always choose the **Do not share this printer** option.
   Repeat these steps for each additional printer to be installed.

4 Return to the Print Share Configuration Wizard, and proceed to the next step to configure a PrintShare resource in your service group and bring it online.

   **To configure a PrintShare resource for the service group**

   1 On the Add Printer panel, click **Next**.
2 On the Printer List panel, specify the printers to be included in the print share service group and then click Next.

![Printer List panel](image)

- **Printer List**: Click to select the printer, and then click the right arrow to include the selected printers in your service group. To remove a selected printer from your service group, click the printer from the Printer Name list and click the left arrow.

- **Share Name**: Type a unique share name for the printer by which it will be known to clients. If you previously chose to share the printer, VCS uses the printer’s share name.

3 On the Service Group Summary panel, review the service group configuration and then click Next. A message appears informing you that the wizard will run commands to modify the service group configuration. Click Yes. The wizard starts...
running commands to create the service group. Various messages indicate the status of these commands.

4 In the completion dialog box, check **Bring the service group online** if you want to bring the service group online on the local system, and then click **Finish**.
Modifying a print share service group using the wizard

The Print Share Configuration Wizard enables you to modify a print share service group.

■ If the print share service group is online, you must run the wizard from a system on which the service group is online. You can then add and remove resources to the configuration using the wizard; you cannot modify resources that are online.

■ To change the online resource attributes, you must take the service group offline. However, the MountV and VMDg (in case of SFW HA), Mount and DiskRes (in case of Windows LDM) and NetAppSnapDrive and NetAppFiler (in case of VCS for Windows) resources for the service group should be online on the node where you run the wizard and offline on all other nodes.

■ If you are running the wizard to remove a node from the service group’s system list, do not run the wizard on the node being removed.

■ If the service group contains resources that were not part of the default service group configuration, then modifying the service group may change those resources. You may then have to manually restore the settings of those resources later.

To modify the print share service group using the Print Share Configuration Wizard

1 Start the Print Share Configuration Wizard on a system on which the print share service group is online. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Print Share Configuration Wizard)

2 Read the information on the Welcome panel and click Next.

3 On the Wizard Options panel, click Modify service group, select the service group to be modified, and click Next.

4 Follow the wizard instructions and make desired modifications to the service group configuration.

See “Creating a print share service group using the wizard” on page 340 for more information about the configuration wizard.

If you are modifying the service group to remove a PrintShare resource, make sure you offline the resource before deleting it.
Deleting a print share service group using the wizard

This section describes steps to delete a print share service group using the configuration wizard.

To delete the print share service group using the Print Share Configuration Wizard

1. Start the Print Share Configuration Wizard on a system configured to host the print share service group. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Print Share Configuration Wizard)

2. Review the information in the Welcome panel and click Next.

3. In the Wizard Options panel, click Delete service group, select the service group to be deleted, and click Next.

4. In the Service Group Summary panel, click Next.

5. A message appears informing you that the wizard will run commands to delete the service group. Click Yes to delete the service group.

6. Click Finish.
Configuring Microsoft virtual machines

The MSVirtualMachine agent provides high availability to virtual machines created using Microsoft Virtual Server on Windows 2003 systems. Before configuring a virtual machine, review the resource types and attribute definitions of the MSVirtualMachine agent, described in the Veritas Cluster Server Bundled Agents Reference Guide.

Before configuring Microsoft virtual machines in VCS

Note the following prerequisites before configuring Microsoft virtual machines in a VCS environment:

- Verify Microsoft Virtual Server is installed and configured identically on all nodes hosting the service group.
- Install the operating system and the applications that you want to make highly available on the virtual machine.
- Install and configure Virtual Machine Additions on each virtual machine if you plan to enable detailed monitoring for the virtual machine resources.
- Verify the Microsoft Virtual Server configuration files reside locally on each node.
- Make sure the name of the virtual machine is unique in the cluster.
- Verify that you have local administrator privileges on the system where you run the wizard.
- If you have configured a firewall, add the following to the firewall Exceptions list:
  - Port 14150 or the VCS Command Server service, %vcs_home%in\CmdServer.exe
    Here, %vcs_home% is the installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.
  - Port 14141
    For a detailed list of services and ports used by SFW HA, refer to the Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide.
- Verify that the VCS engine, HAD, is running on the system from which you run the wizard.
- Disable the firewall on each node that will host the service group.
- You must have the following information ready. The wizard will prompt you for this information:
Creating the virtual machine service group using the wizard

The Microsoft Virtual Machine Configuration Wizard creates and modifies service groups for Microsoft virtual machines, making virtual machines highly available.

The wizard duplicates the virtual machine and its network configuration on other nodes in the cluster. If the wizard discovers a virtual machine with the same name on another node, the wizard does not duplicate the virtual machine. The wizard does not duplicate virtual hard disks.

You must create a different service group for each virtual machine.

To configure Microsoft virtual machine service group using the Microsoft Virtual Machine Configuration Wizard

   Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Microsoft Virtual Machine Configuration Wizard.

2. Review the information in the Welcome panel and click Next.

3. In the Wizard Options panel, click Create service group and click Next.

4. Enter a name for the service group and specify the systems on which to configure the service group.
   - Enter a name for the service group.
   - In the Available Cluster Systems box, select the systems on which to configure the service group and click the right arrow to move the systems to the service group’s system list. To remove a system from the service group’s system list, click the system in the Systems in Priority Order box and click the left arrow.
   - To change a system’s priority in the service group’s system list, click the system from the Systems in Priority Order and click the up and down arrows. System priority defines the order in which service groups are failed over to systems. The system at the top of the list has the highest priority while the system at the bottom of the list has the lowest priority.
   - Click Next. The wizard then starts validating your configuration. Various messages indicate the validation status.
On the Microsoft Virtual Machine Group Configuration panel, specify details about the virtual machine and then click Next.

■ Select the virtual machine.

■ For each virtual disk, specify a destination folder where the virtual hard disk files will be moved. Click the Browse icon to browse for folders.

■ To enable detail monitoring for the virtual machine, check the Monitor Heartbeats check box and in the No. of Monitor Cycles field, type failed heartbeat threshold. The threshold defines the number of consecutive monitor cycles the agent waits to detect heartbeats from the virtual machine before declaring the resource as faulted.

■ Check the Configure NetApp SnapMirror Resource(s) check box if you wish to set up a disaster recovery configuration. This is applicable in case of VCS for Windows only.

The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration.

Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site.

Select an adapter corresponding to the virtual machine on each system.

■ For each system in the cluster, enter or click a network adapter name to be associated with the network adapters on the virtual machine. To view the adapters associated with a system, click the Adapter Display Name field and click the arrow.

The fields for the virtual IP address and subnet mask are disabled by design.

■ Click Next.
7 This is applicable in case of VCS for Windows only. On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click **Next**.

If you are configuring multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

8 Review the service group configuration.

- The Resources box lists the configured resources. Click on a resource to view its attributes and their configured values in the Attributes box.
- The wizard assigns unique names to resources. Change names of resource, if required.
  - To edit a resource name, select the resource name and either click it or press the F2 key. Press Enter after editing each resource name. To cancel editing a resource name, press Esc.
- Click **Next**.
- A message appears informing you that the wizard will run commands to modify the service group configuration. Click **Yes**.
  - The wizard starts running commands to create the service group. Various messages indicate the status of these commands.

9 In the completion dialog box, select the check box if you want to bring the service group online on the local system.

10 Click **Finish**.

**Note:** For this release, you must configure the virtual network associated with the virtual machine manually on each node in the cluster. Do not switch the service group before configuring the network.
Configuring IIS sites

When configuring the IIS agent to monitor a Web site, you can monitor associated application pools in the following ways:

- Configure a resource to monitor the Web site and define options to monitor associated application pools within the same resource.
- Configure a resource to monitor the IIS site only. Configure additional resources to monitor specific application pools.

VCS provides several ways to configure the agent, including the configuration wizard, Cluster Manager (Java console), and the command line. This section provides instructions on how to use the wizard to configure sites.

To configure IIS agent on Windows Server 2008 Server Core, you must first install IIS 7.0 in the specified order and then manually add the required resources and configure the service group.

See “Installing IIS 7.0 on Windows Server 2008 Server Core” on page 358 for instructions on how to install IIS 7.0 on Server Core.

You can perform the manual configuration steps either directly on the Server Core machine using the command line, or remotely using the Cluster Manager (Java console).

See “Administering the cluster from Cluster Manager (Java console)” on page 161.

See “Administering the cluster from the command line” on page 259.

**Note:** If you have configured a firewall, add ports 14141 and 14150 to the exceptions list.

Before configuring the agent, review the agent’s resource type definition and attribute descriptions in the *Veritas Cluster Server Bundled Agents Reference Guide*. Also, review the sample configurations and resource dependency graphs.

Before configuring IIS sites

Note the following prerequisites before configuring IIS sites:

- Verify IIS is installed and configured identically on all nodes hosting the service group. Verify the sites to be monitored are on shared storage.
- For IIS 7.0 on Windows Server 2008, you must install the following components:
  - IIS 6 Metabase Compatibility
  - IIS 6 WMI Compatibility
Configuring resources and applications in VCS

Configuring IIS sites

These options are available under Management Tools on the Role Services page of the Add Roles Wizard.

These components are required for the IIS agent to function on Windows Server 2008.

For IIS 7.0 on Windows Server 2008 Server Core, you must install IIS in the specified order.

See “Installing IIS 7.0 on Windows Server 2008 Server Core” on page 358 for instructions.

- Do not use the IIS agent to configure SMTP and NNTP sites if you have Microsoft Exchange installed.
- Change the default home directory path for all IIS sites to monitored to a location on the shared storage. See the IIS documentation for instructions.
- Verify the port numbers assigned to IIS sites are not used by other programs.
- Synchronize the IIS configuration on all nodes hosting the service group. See “Synchronizing IIS configuration on Windows 2003” on page 357 for instructions.

Synchronizing IIS configuration on Windows 2003

Synchronize the IIS configuration on all nodes that will host the IIS service group. Complete the following steps.

To synchronize the IIS configuration on Windows 2003 systems

1. Run the script iiscnfg.vbs, located at %systemroot%\System32. The script copies the IIS metabase from the local system to the target system. For example, the following command copies the IIS metabase to target_system. You must enter a valid user name and password for the target system.

   %systemroot%\System32> iiscnfg /copy /ts target_system /tu user_name /tp password

2. Stop and restart IIS Admin Service on all nodes.
Installing IIS 7.0 on Windows Server 2008 Server Core

Complete the following steps.

To install IIS 7.0 on Windows Server 2008 Server Core

1. Type the following at the command prompt:
   
   ```
   C:\>start /w pkgmgr
   /iu:IIS-WebServerRole;IIS-WebServer;IIS-CommonHttpFeatures;
   IIS-StaticContent;IIS-DefaultDocument;IIS-DirectoryBrowsing;
   IIS-HttpErrors;IIS-HttpRedirect;IIS-ApplicationDevelopment;
   IIS-ASP;IIS-CGI;IIS-ISAPIExtensions;IIS-ISAPIFilter;
   IIS-ServerSideIncludes;IIS-HealthAndDiagnostics;
   IIS-HttpLogging;IIS-LoggingLibraries;IIS-RequestMonitor;
   IIS-HttpTracing;IIS-CustomLogging;IIS-ODBCLogging;IIS-Security;
   IIS-BasicAuthentication;IIS-WindowsAuthentication;
   IIS-DigestAuthentication;
   IIS-ClientCertificateMappingAuthentication;
   IIS-IISCertificateMappingAuthentication;
   IIS-URLAuthorization;IIS-RequestFiltering;IIS-IPSecurity;
   IIS-Performance;IIS-HttpCompressionStatic;
   IIS-HttpCompressionDynamic;IIS-WebServerManagementTools;
   IIS-ManagementScriptingTools;IIS-IIS6ManagementCompatibility;
   IIS-Metabase;IIS-WMICompatibility;IIS-LegacyScripts;
   IIS-FTPPublishingService;WAS-WindowsActivationService;
   IIS-FTPPublishingService;IIS-FTPServer
   ```

2. Verify that all the components specified in the earlier step have successfully installed. Type the following at the command prompt:
   
   ```
   C:\>notepad C:\windows\logs\cbs\cbd.log
   ```
   
   This opens the log file, cbd.log, in the Notepad text editor.

3. Check the entries in the log file, cbd.log. The last log entry should resemble the following:
   
   ```
   Info CBS Pkgmgr: return code: 0x0
   ```
   
   This message indicates that all the components are installed successfully.

4. Run the oclist command to verify that the following components are installed:
   
   ```
   IIS-WebServerRole; IIS-WebServer; IIS-IIS6ManagementCompatibility;
   IIS-Metabase; IIS-WMICompatibility; IIS-FTPPublishingService;
   WAS-WindowsActivationService; IIS-FTPPublishingService; IIS-FTPServer
   ```
   
   Type the following at the command prompt:
   
   ```
   C:\>oclist
   ```

5. Repeat the steps on all the nodes on which you wish to configure the IIS service group.
Before you configure an IIS service group

Note the following prerequisites before you configure an IIS service group:

- Verify that you have local administrator privileges on the system where you run the wizard.
- If you have configured a firewall, add the following to the firewall exceptions list:
  - Port 14150 or the VCS Command Server service,
    %vcs_home%\bin\CmdServer.exe
    Here, %vcs_home% is the installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.
  - Port 14141
- For a detailed list of services and ports used by SFW HA, refer to the Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide.
- Verify that the VCS high availability engine, HAD, is running on the system from which you run the wizard.
- Mount the drives (in case of SFW HA), or connect the LUNs (in case of VCS for Windows) containing the shared directories on the system from which you run the wizard. Unmount the drives or LUNs from other systems in the cluster.
  See “Managing shared storage using Windows Logical Disk Manager” on page 309 for more information.
  See for “Managing storage in a Network Appliance storage environment” on page 313 more information.
  See for “Managing shared storage using SFW” on page 315 more information.
- If your storage is SCSI-3 compliant and you wish to use SCSI-3 persistent reservations, enable SCSI-3 support using Veritas Enterprise Administrator (VEA). This is applicable for SFW HA only.
- Verify that you have the following information ready. The wizard will prompt you for this information:
  - IIS sites to be monitored.
  - Application pools associated with each site.
  - Port numbers associated with each site.
  - Virtual IP addresses and computer names associated with the sites. The virtual IP addresses and the virtual computer names must have forward and reverse entries in the DNS.
Creating an IIS service group using the wizard

The IIS Configuration Wizard enables you to create and modify IIS service groups, making sites highly available in VCS cluster.

The wizard creates one resource for each IIS site and its associated application pools; the wizard does not create resources that monitor only application pools.

To create an IIS service group using the IIS Configuration Wizard

1. Start the IIS Configuration Wizard.
   
   Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > IIS Configuration Wizard

2. Review the information in the Welcome panel and click Next.

3. On the Wizard Options panel, click Create service group and click Next.

4. On the Service Group Configuration panel, specify the service group details and then click Next. The wizard then starts validating your configuration. Various messages indicate the validation status.

![IIS Configuration Wizard]

Service Group Name: Type a name for the IIS service group.
Configuring resources and applications in VCS

Configuring IIS sites

On the Configure IIS Sites panel, add and remove sites from the service group, configure IP addresses, ports, and virtual computer names, optionally choose to configure NetApp SnapMirror resources, and then click Next.

Available Cluster Systems
Select the systems on which to configure the service group and click the right arrow to move the systems to the service group’s system list.

To remove a system from the service group’s system list, click the system in the Systems in Priority Order box and click the left arrow.

To change a system’s priority in the service group’s system list, click the system from the Systems in Priority Order and click the up and down arrows.

System priority defines the order in which service groups are failed over to systems. The system at the top of the list has the highest priority while the system at the bottom of the list has the lowest priority.

5 On the Configure IIS Sites panel, add and remove sites from the service group, configure IP addresses, ports, and virtual computer names, optionally choose to configure NetApp SnapMirror resources, and then click Next.

Add
Check the check box corresponding to the site to be configured in VCS.

IP
Type the virtual IP address for each site to be configured. Make sure that each virtual IP address is associated with only one virtual computer name and vice-versa.
Configuring resources and applications in VCS

Configuring IIS sites

6 On the Network Configuration panel, specify information related to the virtual IP addresses and click **Next**.

| Port | Type the port number for each site to be configured. |
| Configure NetApp | This is applicable in case of VCS for Windows only. Check the **Configure NetApp SnapMirror Resource(s)** check box if you wish to set up a disaster recovery configuration. The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration. Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site. |
| IP Address | Displays the virtual IP addresses. The wizard groups systems by the virtual IP addresses associated with the systems. |
| Subnet Mask | Type the subnet mask associated with each virtual IP address. |
| Adapter Name | Select the adapter associated with the virtual IP address on each system. |

7 This is applicable in case of VCS for Windows only.
On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click Next.

If you are configuring multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

8 On the Application Pool Configuration panel, select the monitoring options for application pools associated with each site and click Next.

Site Name Displays the site names.

AppPoolMon For each site, select the monitoring options from the AppPoolMon list.

Choose from the following options in the drop-down list:

- **NONE**: The agent will not monitor the application pool associated with the site.
- **DEFAULT**: Starts and monitors the root application pool associated with the site.
- **ALL**: Starts all application pools associated with the site and monitors root application pool.

9 On the Service Group Summary panel, review the service group configuration and click Next. Click Yes on the message that informs you that
the wizard will run commands to modify the service group configuration. The wizard starts running commands to create the service group. Various messages indicate the status of these commands.

Resources Displays a list of configured resources. The wizard assigns unique names to resources. Change the names of resource, if required.

To edit a resource name, select the resource name and either click it or press the F2 key. Edit the resource name and then press the Enter key to confirm the changes. To cancel editing a resource name, press the Esc key.

Attributes Displays the attributes and their configured values, for a resource selected in the Resources list.

10 In the completion dialog box, check **Bring the service group online** if you want to bring the service group online on the local system, and then click **Finish.**
Modifying an IIS service group using the wizard

The IIS configuration wizard enables you to modify an IIS service group.

- If the IIS service group is online, you must run the wizard from a system on which the service group is online. You can then add and remove resources to the configuration using the wizard; you cannot modify resources that are online.

- To change the online resource attributes, you must take the service group offline. However, the MountV and VMDg (in case of SFW HA), Mount and DiskRes (in case of Windows LDM) and NetAppSnapDrive and NetAppFiler (in case of VCS for Windows) resources for the service group should be online on the node where you run the wizard and offline on all other nodes.

- If you are running the wizard to remove a node from the service group's system list, do not run the wizard on the node being removed.

- If the service group contains resources that were not part of the default service group configuration, then modifying the service group may change those resources. You may then have to manually restore the settings of those resources later.

To modify the IIS service group using the IIS Configuration Wizard

1. Start the IIS Configuration Wizard.
   
   **Start** > **All Programs** > **Symantec** > **Veritas Cluster Server** > **Configuration Tools** > **IIS Configuration Wizard**.
   
   or
   
   Click **Start** > **All Programs** > **Symantec** > **Veritas Cluster Server** > **Solutions Configuration Center** to start the Solutions Configuration Center (SCC).

   In the SCC, click the **Solutions** tab and under High Availability Configuration Wizards click the **Launch** button for the IIS Configuration Wizard.

2. Review the information in the Welcome panel and click **Next**.

3. In the Wizard Options panel, click **Modify service group**, select the service group to be modified, and click **Next**.

4. Follow the wizard instructions and make desired modifications to the service group configuration.

   See “Creating an IIS service group using the wizard” on page 360.
Deleting an IIS service group using the wizard

This section describes steps to delete an IIS service group using the configuration wizard.

To delete the IIS service group using the IIS Configuration Wizard

1  Start the IIS Configuration Wizard on a system configured to host the IIS service group. (Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > IIS Configuration Wizard)

2  Review the information in the Welcome panel and click Next.

3  In the Wizard Options panel, click Delete service group, select the service group to be deleted, and click Next.

4  In the Service Group Summary panel, click Next. A message appears informing you that the wizard will run commands to delete the service group. Click Yes to delete the service group.

5  Click Finish.
Configuring services

This section provides an overview of the steps involved in configuring services in a VCS cluster.

- To start, stop, and monitor a service, use the GenericService agent.
- To monitor a service, use the ServiceMonitor agent.

About configuring a service using the GenericService agent

The GenericService agent starts, stops, and monitors services. Before configuring the service group, review the resource types and attribute definitions of the GenericService agent described in the *Veritas Cluster Server Bundled Agents Reference Guide*.

You can configure the GenericService agent manually, as described below, or by using the Application Configuration Wizard.

See “Configuring applications using the Application Configuration Wizard” on page 390 for instructions.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using the command line, or remotely using the Cluster Manager (Java console).

See “Administering the cluster from Cluster Manager (Java console)” on page 161.

See “Administering the cluster from the command line” on page 259.

*Note:* If you have configured Windows Firewall, add ports 14141 and 14150 to the Exceptions list.

Before you configure a service using GenericService agent

Note the following prerequisites before you configure a service using the VCS GenericService agent:

- Change the startup type of the generic service to manual on all nodes that will be part of the service group.
- Ensure that the service is stopped on all the nodes that will be part of the service group.
- If monitoring the service in a user-context, configure the service to start in the context of the specified user account. Make sure the check box for *Allow service to interact with desktop* is unchecked.
To change a service startup type to Manual
1. Open the Services Control Manager.
2. Right-click the service and click Properties.
3. In the Properties dialog box, click the General tab.
4. From the Startup Type list, select Manual.
5. Click OK.
6. Close the Services Control Manager.

To configure a service to start in a user-context
1. Open the Services Control Manager.
2. Right-click the service and click Properties.
3. In the Properties dialog box, click the LogOn tab.
4. Click This Account.
5. Click Browse to browse existing user accounts.
6. In the Select User dialog box, click the user in whose context you want to run the service and click OK.
7. Enter the password for the selected user.
8. Click OK and close the Services Control Manager.

Configuring a service using the GenericService agent

Complete the following steps to configure a service using the GenericService agent manually.

To configure a service using GenericService agent
1. In your service group, create a resource of type GenericService. See “Adding a resource” on page 223 for instructions.
2. Configure the following required attribute for the resource.
   - ServiceName: The name of the service to be monitored, as displayed by SCM.

If required, configure the following optional attributes for the resource:
- UserAccount: A valid user account in whose context the service will be monitored. Username can be of the form username@domain.com or domain.com\username. If you do not specify a value for this attribute, then the user account of the service in the SCM is ignored. To monitor
service under built-in accounts, you must provide explicit values. For example:
- On Windows 2003: User Account="LocalSystem", "Local Service", or “Network Service”. Domain="NT Authority”.
  ■ Password: The password for the user account.
  ■ Domain: The domain name to which the user specified in the UserAccount attribute belongs.

3 Configure other resources in the service group, if required.
4 Bring the GenericService resource, and other resources in the service group, online.

About configuring a service using the ServiceMonitor agent

The ServiceMonitor agent monitors a service or starts a script that monitors a service. Before configuring the service group, review the resource types and attribute definitions of the agent, described in the Veritas Cluster Server Bundled Agents Reference Guide.

You can configure the agent manually, as described below, or by using the Application Configuration Wizard.

See “Configuring applications using the Application Configuration Wizard” on page 390.

Before you configure a service using the ServiceMonitor agent

Note the following prerequisites before you configure a service using the VCS ServiceMonitor agent:

■ If using the agent to start a script, copy the script a locally on each system in the cluster.
■ If using the agent to monitor a service, start the service in the context of the LocalSystem account or in the context of the user account specified in the configuration.
■ Verify that the user in whose context the service or script needs to be started, exists as a domain user or LocalSystem user.

Configuring a service using the ServiceMonitor agent

Complete the following steps to configure a service using the ServiceMonitor agent manually.
To configure a service using the ServiceMonitor agent

1. In your service group, create a resource of type ServiceMonitor. See “Adding a resource” on page 223 for instructions.

2. Configure the following required attribute for the resource.
   - **ServiceOrScriptName**: The name of the service to be monitored using the Service Control Manager (SCM). When monitoring the service through a user defined script, specify the complete path of the script, including any command-line arguments.

   When monitoring a service through a user-defined script, values for the following attributes also need to be specified:
   - **MonitorService**: Defines whether the agent monitors a service using the SCM or starts a script to monitor a service. If the flag is set to 1, the agent monitors a service specified by the attribute `ServiceOrScriptName`. If set to 0 the agent starts a script specified by the attribute `ServiceOrScriptName`. Default is 1.
   - **MonitorProgTimeout**: The maximum wait time, in seconds, for the agent to receive a return value from the monitor script. This attribute is ignored if the MonitorService flag is set to 1. Default is 30 seconds.

3. Configure other resources in the service group, if required.

4. Bring the ServiceMonitor resource, and other resources in the service group, online.
Configuring processes

Before configuring a Process, review the resource types and attribute definitions of the Process agent described in the *Veritas Cluster Server Bundled Agents Reference Guide*.

You can configure a Process resource either manually, as described below, or by using the Application Configuration Wizard.

See “Configuring applications using the Application Configuration Wizard” on page 390 for instructions.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using the command line, or remotely using the Cluster Manager (Java console).

See "Administering the cluster from Cluster Manager (Java console)” on page 161.

See "Administering the cluster from the command line” on page 259.

**Note:** If you have configured Windows Firewall, add ports 14141 and 14150 to the Exceptions list.

Before you configure processes

Note the following prerequisites before you configure processes:

- The executables configured as the start, stop, and monitor programs must reside on local drives.
- When defining the `StartProgram`, `StopProgram`, or `MonitorProgram` attributes, enclose the path of the executable file in double quotes. *Do not enclose arguments in double quotes*. For example, specify the `StartProgram` attribute in the following format:

  ```
  StartProgram = "executable_pathname" arguments
  ```

Configuring processes using the Process agent

Complete the following steps to configure a process using the VCS Process agent manually.

*To configure a process using the Process agent*

1. In your service group, create a resource of type Process.

   See “Adding a resource” on page 223 for instructions.
2 Configure the following required attribute for the resource.
   - StartProgram: The process to be monitored by the agent. You must specify the complete path of the executable, its file extension, and command-line arguments, if any. If you define the start program as a script to launch another program, you must specify the monitor program in the configuration file.
     If you define the start program as a script (a perl script, or a vbs script), the start program should be the program that interprets the script (perl.exe, or cscript.exe) and the script itself should be passed as an argument.

Configure the following optional attributes, if required:
   - StartupDirectory: The startup directory for the process indicated by the StartProgram attribute.
   - MonitorProgram: A program that monitors the process specified as the start program. You must specify the complete path of the executable, its file extension, and command-line arguments, if any. If you do not specify a value for this attribute, VCS monitors the start program. However, if the start program is a script to launch another program, you must specify a monitor program.
   - MonitorProgramTimeout: The maximum wait time, in seconds, for the agent to receive a return value from the monitor routine. This attribute is ignored if the monitor program is not specified.

3 Configure other resources in the service group, if required.

4 Bring the Process resource, and other resources in the service group, online.
Configuring a Microsoft Message Queuing (MSMQ) service group

VCS provides several ways to configure a Microsoft Message Queuing (MSMQ) service group that include the MSMQ Configuration Wizard, the Enterprise Vault Cluster Setup Wizard, Cluster Manager (Java Console), Web Console, and the command line.

To create an MSMQ service group from the Cluster Manager (Java Console), you can use the MSMQ service group configuration template, MSMQVMGroup (for SFW), or MSMQNetAppGroup (for NetApp). These templates are installed at \%vcs_home%\templates directory.

Here, \%vcs_home% is the default product installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.

Launch the Service Group Configuration Wizard (Tools > Configuration Wizard) from the Cluster Manager (Java Console) and use these templates to configure the respective application service groups.

The following sections describe how to configure an MSMQ service group using the MSMQ Configuration Wizard.

You can use the MSMQ Configuration Wizard to configure a service group for MSMQ that is installed in Active Directory or in Workgroup mode.

Symantec recommends that you use the MSMQ Configuration Wizard to create the MSMQ resource and other resources that it depends upon.

Make sure that you review the resource types and attribute definitions of the MSMQ agent in the Veritas Cluster Server Bundled Agents Reference Guide.

Note: Cluster support for MSMQ triggers is not available in this release. In domain mode MSMQ installation (MSMQ 3.0 on Windows 2003, MSMQ 4.0 on Windows Server 2008), if Routing Support is selected while installing MSMQ, it is not supported.

Before you configure the MSMQ service group

Note the following prerequisites before you configure the MSMQ service group:

- Remove the Message Queuing Triggers service if it is already installed. Cluster support for MSMQ Triggers service is not available in this release.
- Create volumes or LUNs for the MSMQ data and registry replication information (RegRep) and then mount or connect the volumes or LUNs on the node where you run the wizard.
You can use a single volume for both MSMQ data and registry information. Symantec recommends that you use separate volumes for these components.

See "Managing shared storage using Windows Logical Disk Manager" on page 309 for more information.

See for "Managing storage in a Network Appliance storage environment" on page 313 more information.

See for "Managing shared storage using SFW" on page 315 more information.

- Create directories for MSMQ data and registry information on the mounted volumes. For example, if X: is the volume, then X:\MSMQ\Storage can be the storage path for MSMQ.

- If MSMQ is integrated with Windows Active Directory (AD), then ensure that the value of the Lanman resource attributes ADUpdateRequired and ADCriticalForOnline is set to 1, after the service group is configured.

**Note:** You may receive an error when you try to read messages from a remote public queue in Microsoft Message Queuing. See article 889860 in the Microsoft Knowledge Base for more information. To overcome this problem, set the value of the Lanman resource attributes DNSUpdateRequired and DNSCriticalForOnline to 1.

- Verify that all the existing services that are dependent on the default MSMQ service are in the STOPPED state.

- If MSMQ is installed in Domain Mode, perform the following steps before you bring the MSMQ resource online for the first time:
  - First, bring the Lanman resource online in the service group.
  - Next, in the Windows AD, enable the 'Create All Child Objects' privilege for the VCS Helper Service user account (HAD Helper) on the MSMQ virtual server.

**Note:** You do not need to add this privilege if the VCS Helper Service user account belongs to the Domain Administrator group.

- Keep the following information ready; the wizard will prompt you for these details:
  - A unique virtual server name for the MSMQ server.
  - A unique virtual IP address for the MSMQ server.

Ensure that there is only one IP resource per MSMQ resource. If there are multiple MSMQ resources that use the same IP resource, only one
Configuring resources and applications in VCS

Configuring a Microsoft Message Queuing (MSMQ) service group

MSMQ resource will remain online, and the rest will go into the UNKNOWN state.

Creating the MSMQ service group using the wizard

Complete the following steps to create an MSMQ service group using the MSMQ Configuration Wizard.

To create an MSMQ service group using the MSMQ Configuration Wizard

1. Start the MSMQ Configuration Wizard.
   - Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > MSMQ Configuration Wizard.
   - or
   - Click Start > All Programs > Symantec > Veritas Cluster Server > Solutions Configuration Center to start the Solutions Configuration Center (SCC).
   - In the SCC, click the Solutions tab and under High Availability Configuration Wizards click the Launch button for the MSMQ Configuration Wizard.

2. Review the information on the Welcome panel and then click Next.

3. On the Wizard Options panel click Create service group and then click Next.

4. On the Service Group Configuration panel, specify the service group name, choose the systems for the service group, and then click Next.
   - The wizard then starts validating your configuration. Various messages indicate the validation status.

   - **Service Group Name**: Type a name for the MSMQ service group.

   - **Available Cluster Systems**: Select the systems on which to configure the service group and click the right arrow to move the systems to the service group's system list.
     - To remove a system from the service group's system list, click the system in the Systems in Priority Order box and click the left arrow.
     - To change a system's priority in the service group's system list, click the system from the Systems in Priority Order and click the up and down arrows.

   System priority defines the order in which service groups are failed over to systems. The system at the top of the list has the highest priority while the system at the bottom of the list has the lowest priority.
5 On the Virtual Server Configuration panel, specify information related to your network and then click **Next**.

Virtual Server Name: Type a unique name for the MSMQ virtual server. This is the name by which clients will connect to the MSMQ server. The virtual name must not exceed 16 characters.

Virtual IP Address: Type a unique virtual IP address for the MSMQ virtual server.

Subnet Mask: Type the subnet to which the virtual IP belongs.

Adapter Display Name: For each system, select the public network adapter name. This field displays the TCP/IP enabled adapters on a system, including the private network adapters, if applicable. To view the adapters associated with a system, click the Adapter Display Name field and click the arrow. Verify that you select the adapters assigned to the public network, not the private.
Advantages Settings

Click **Advanced Settings** if you wish to configure the Lanman agent to perform Windows AD update. These settings are applicable to the Lanman resource in the service group.

On the Lanman Advanced Configuration dialog box, complete the following:

1. Check **Active Directory Update required** check box to enable the Lanman agent to update the Active Directory with the virtual name. This sets the Lanman agent attributes ADUpdateRequired and ADCriticalForOnline to true.

2. In the Organizational Unit field, type the distinguished name of the Organizational Unit for the virtual server in the format:

   \texttt{CN=containername,DC=domainname,DC=com}.

   To browse for an OU, click the ellipsis (...) button and search for the OU using the Windows Find Organization Units dialog box.

   By default, the Lanman resource adds the virtual server to the default container "Computers."

3. Click **OK**.

   The user account for VCS Helper service must have adequate privileges on the specified container to create and update computer accounts.
6 On the MSMQ and RegRep Directory Details panel, specify the MSMQ and registry replication directories and then click **Next**.

**MSMQ Directory**
- Specify the directory path for storing the MSMQ data. You can either type the path or click the ellipsis button (\(\ldots\)) to browse for a directory. The MSMQ agent uses the specified MSMQ directory to store all the message queues.

**Replication Directory**
- Specify the directory path for storing the MSMQ registry data. You can either type the path or click the ellipsis button (\(\ldots\)) to browse for a directory. The Registry Replication agent uses the specified regrep directory to store the MSMQ registry related information.
379 Configuring resources and applications in VCS

Configuring a Microsoft Message Queuing (MSMQ) service group

This is applicable in case of VCS for Windows and in a NetApp storage environment.

On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click Next.

If you are configuring Multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

Configure NetApp SnapMirror Resource(s)

This is applicable in case of VCS for Windows only.

Check the Configure NetApp SnapMirror Resource(s) check box if you wish to set up a disaster recovery configuration. The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration.

Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site.

7 This is applicable in case of VCS for Windows and in a NetApp storage environment.

On the Initiator Selection panel, select the initiator for the virtual disk from the list of available initiators displayed for each cluster node, and then click Next.

If you are configuring Multipath I/O (MPIO) over Fibre Channel (FC), you must select at least two FC initiators for each cluster node. Note that the node from which you run this wizard already has an initiator selected by default. This is the initiator that was specified when you connected the LUNs to this cluster node.

8 On the Service Group Summary panel, review the service group configuration and click Next.

Click Yes on the message that prompts you that the wizard will run commands to modify the service group configuration.
The wizard starts running commands to create the service group. Various messages indicate the status of these commands.

Resources      Displays a list of configured resources. The wizard assigns unique names to resources. Change the names of resource, if required.
               To edit a resource name, select the resource name and either click it or press the F2 key. Edit the resource name and then press the Enter key to confirm the changes. To cancel editing a resource name, press the Esc key.

Attributes     Displays the attributes and their configured values, for a resource selected in the Resources list.

9 In the completion dialog box, check **Bring the service group online** check box if you want to bring the service group online on the local system and then click **Finish**.
This completes the MSMQ service group configuration. You can now create, delete, and modify message queues on the virtual MSMQ. Use the VCS Application Manager utility.
See “About the VCS Application Manager utility” on page 417.
Modifying an MSMQ service group using the wizard

The MSMQ Configuration Wizard enables you to modify an MSMQ service group.

- If the MSMQ service group is online, you must run the wizard from a system on which the service group is online. You can then add and remove resources to the configuration using the wizard; you cannot modify resources that are online.

- To change the online resource attributes, you must take the service group offline. However, the MountV and VMDg (in case of SFW HA), Mount and DiskRes (in case of Windows LDM) and NetAppSnapDrive and NetAppFiler (in case of VCS for Windows) resources for the service group should be online on the node where you run the wizard and offline on all other nodes.

- If you are running the wizard to remove a node from the service group's system list, do not run the wizard on the node being removed.

- If the service group contains resources that were not part of the default service group configuration, then modifying the service group may change those resources. You may then have to manually restore the settings of those resources later.

To modify an MSMQ service group using the MSMQ Configuration Wizard

1. Start the MSMQ Configuration Wizard on a system on which the MSMQ service group is online.
   Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > MSMQ Configuration Wizard.

2. Read the information on the Welcome panel and click Next.

3. On the Wizard Options panel, click Modify service group, select the service group to be modified, and click Next.

4. Follow the wizard instructions and make desired modifications to the service group configuration.
   See “Creating the MSMQ service group using the wizard” on page 375.
   If you are modifying the service group to remove an MSMQ resource, make sure you offline the resource before deleting it.
Configuring infrastructure and support agents

This section provides an overview of the steps in configuring the VCS infrastructure and support agents.

- To configure notification in your cluster, use the NotifierManager (NotifierMngr) agent.
  See “Configuring notification” on page 383 for instructions.
- To configure registry replication, use the Registry Replication (RegRep) agent.
  See “Configuring registry replication” on page 383 for instructions.
- To configure web applications, use the VRTSWebApp agent.
  See “Configuring Veritas Web applications” on page 386 for instructions.
- To configure a dummy resource to mirror the state of another resource, use the Proxy agent.
  See “Configuring a proxy resource” on page 387 for instructions.
- To determine the state of a service group with no OnOff resources, use the Phantom agent.
  See “Configuring a phantom resource” on page 387 for instructions.
- To test VCS functionality, configure the various file agents.
  See “Configuring file resources” on page 388 for instructions.
- To monitor or manage a service group that exists in a remote cluster, use the RemoteGroup agent.
  See “Configuring a RemoteGroup resource” on page 388 for instructions.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using the command line, or remotely using the Cluster Manager (Java console).

See “Administering the cluster from Cluster Manager (Java console)” on page 161.
See “Administering the cluster from the command line” on page 259.

Note: If you have configured Windows Firewall, add ports 14141 and 14150 to the Exceptions list.

Before configuring the service group, review the resource types and the attribute definitions of the agents, described in the Veritas Cluster Server Bundled Agents Reference Guide.
Configuring notification

Use the NotifierMngr agent to set up notification in your cluster. Review the information on about how VCS handles notification.

See “VCS event notification” on page 535.

VCS provides a wizard to set up notification.

See “Setting up VCS event notification using the Notifier wizard” on page 250.

Configuring registry replication

The Registry Replication (RegRep) agent replicates the registry of the active cluster node.

Configuration tasks

1. Configure an exclusive MountV resource (in case of SFW HA) or a NetAppSnapDrive resource (in case of VCS for Windows) for the Registry Replication agent. Verify that no other applications use this resource.

   See “Configuring shared storage” on page 308 for instructions.

2. Create a resource of type RegRep.

   See “Adding a resource” on page 223 for instructions.

3. Configure the following required attributes for the resource.

   - **Keys**: The list of registry keys to be monitored. From the ‘name-value’ pair of a registry key, you must provide the name of the registry keys to be synchronized and not the value for that key.
     When defining the keys, you must use the abbreviations listed in “Configuring registry keys” on page 384. For excluding certain keys from being replicated, see the instructions listed in “Excluding keys” on page 384. For instructions on replicating registry keys without replicating the subkeys, see “Ignoring subkeys” on page 385.
     Do not configure more than 63 keys for a single RegRep resource otherwise the resource will go in an UNKNOWN state.

   - **MountResName or FilerResName**: The name of the MountV resource (in case of SFW HA) or NetAppSnapDrive resource (in case of VCS for Windows) on which the Registry Replication agent depends. The resource specifies the mount drive or LUN on the shared disk where the log file is created.

   - **ReplicationDirectory**: The directory on the shared disk in which the registry changes are logged.

4. Configure other resources for the service group, if required.
5 Link the RegRep and MountV (in case of SFW HA) or NetAppSnapDrive (in case of VCS for Windows) resources such that the RegRep resource depends on the MountV (in case of SFW HA) or NetAppSnapDrive (in case of VCS for Windows) resource. See “Linking resources” on page 236 for instructions.

6 Bring the RegRep resource, and other resources in the service group, online.

Configuring registry keys
To configure a registry key to be replicated or excluded, use the abbreviation corresponding to the registry hive, as listed below:

<table>
<thead>
<tr>
<th>Registry Hive</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>HKEY_LOCAL_MACHINE</td>
<td>HKLM</td>
</tr>
<tr>
<td>HKEY_CURRENT_USER</td>
<td>HKCU</td>
</tr>
<tr>
<td>HKEY_USERS</td>
<td>HKU</td>
</tr>
<tr>
<td>HKEY_CURRENT_CONFIG</td>
<td>HKCC</td>
</tr>
<tr>
<td>HKEY_CLASSES_ROOT</td>
<td>HKCR</td>
</tr>
</tbody>
</table>

Excluding keys
This section describes the algorithm the Registry Replication agent uses while excluding keys. For example, assume a registry key KEY_X has a subkey of KEY_Y, which has a subkey KEY_Z. This key would appear as KEY_X\KEY_Y\KEY_Z in the Registry Editor. The following table describes various scenarios of keys marked for replication and for exclusion. The Result column describes the agent behavior in these scenarios.

<table>
<thead>
<tr>
<th>Keys for Replication</th>
<th>Exclude Keys</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY_X</td>
<td>KEY_Y\KEY_Z</td>
<td>KEY_Y is excluded. So is KEY_Z.</td>
</tr>
<tr>
<td>KEY_X</td>
<td>KEY_Y</td>
<td>KEY_Y is excluded. So is KEY_Z.</td>
</tr>
<tr>
<td>KEY_X</td>
<td>KEY_X</td>
<td>KEY_X is not excluded and an error message is logged.</td>
</tr>
</tbody>
</table>
Configuring resources and applications in VCS

Configuring infrastructure and support agents

Ignoring subkeys

Use the `IgnoreSubKeys` option for the `Keys` attribute to prevent the RegistryReplication agent from replicating the subkeys. The following table describes possible combination of values for the `Keys` attribute. The Result column describes the agent behavior in these scenarios:

<table>
<thead>
<tr>
<th>Value Specified for “Keys” Attribute</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>HKLM\SOFTWARE\VERITAS\VCS</em></td>
<td>Replicates the subkeys</td>
</tr>
<tr>
<td><em>HKLM\SOFTWARE\VERITAS\VCS</em>=IgnoreSubKeys</td>
<td>Does not replicate the subkeys</td>
</tr>
<tr>
<td><em>HKLM\SOFTWARE\VERITAS\VCS</em>=IgnoreSubKeys:Yes</td>
<td>Does not replicate the subkeys</td>
</tr>
<tr>
<td><em>HKLM\SOFTWARE\VERITAS\VCS</em>=IgnoreSubKeys:No</td>
<td>Replicates the subkeys</td>
</tr>
<tr>
<td><em>HKLM\SOFTWARE\VERITAS\VCS</em>=&lt;any other value&gt;</td>
<td>Replicates the subkeys</td>
</tr>
</tbody>
</table>

**Additional considerations for using IgnoreSubKeys**

Symantec recommends not to set the `IgnoreSubKeys` value when the RegRep resource is online. Even if the value is set with the resource online, the changes will be applicable after the next online routine.
Configuring Veritas Web applications

The VRTSWebApp agent brings web applications online, takes them offline, and monitors their status. The agent provides high availability to Veritas Web applications, which support Web consoles of various products.

Configuration tasks

1. In your service group, create resources of type NIC and IP. See “Configuring IP addresses in single-adapter systems” on page 318 for instructions.
2. Create a resource of type VRTSWebApp.
3. Configure the following required attributes for the resource.
   - **AppName**: Name of the application as it appears in the Web server. For example, for VCS, use `vcs`.
   - **InstallDir**: Path to the Web application installation. The Web application must be installed as a .war file with the same name as the AppName parameter. This attribute should point to the directory that contains this .war file.
   - **TimeForOnline**: The time the Web application takes to start after it is loaded into the Web server. This parameter is returned as the exit value of the online script, which inform VCS of the time it needs to wait before calling monitor routine on the Web application resource. Typically, this attribute is at least five seconds.
4. Configure other resources for the service group, if required.
5. Link resources to create the following dependencies:
   - IP resource depends on the NIC resource.
   - VRTSWebApp resource depends on the IP resource.
   See “Linking resources” on page 236 for instructions.
6. Bring the VRTSWebApp resource, and other resources in the service group, online.
Configuring a proxy resource

The Proxy agent monitors and mirrors the state of a resource on a local or remote system in a VCS cluster. Use this agent to reduce overheads in configurations where multiple resources point at the same physical device. For example, if multiple service groups use the same NIC, configure one service group to monitor the NIC and have Proxy resources in the other service groups to mirror the state of the NIC resource.

Configuration tasks

1. Create a resource of type Proxy.
   See “Adding a resource” on page 223 for instructions.
2. Configure the following required attribute for the resource:
   - TargetResName: The name of the target resource whose status is to be monitored and mirrored by the Proxy resource.
   If required, configure the following optional attribute for the resource:
   - TargetSysName: The name of the system associated with the target resource. If this attribute is not specified, the Proxy resource assumes the system is local.
3. Configure other resources for the service group, if required.
4. Bring the Proxy resource, and other resources in the service group, online.

Configuring a phantom resource

A Phantom resource enables VCS to determine the status of service groups that do not include OnOff resources.

Configuration tasks

1. Create a resource of type Phantom.
   See “Adding a resource” on page 223 for instructions.
2. Configure other resources for the service group, if required.
3. Bring the Phantom resource, and other resources in the service group, online.
Configuring file resources

The FileNone, ElifNone, FileOnOff, and FileOnOnly agents help you test VCS functionality. The process of configuring these resources is similar.

- The FileNone agent monitors a file and returns ONLINE if the file exists.
- The ElifNone agent monitors a file and returns ONLINE if the file does not exist.
- The FileOnOff agent creates, removes, and monitors a file.
- The FileOnOnly agent creates and monitors a file.

Configuration tasks

1. In your service group, create a resource of the desired type. See “Adding a resource” on page 223 for instructions.
2. Configure the following required attribute for the resource.
   - PathName: The complete path of the file to be monitored.
3. If required, configure additional resources in the service group.
4. Bring the file resource, and other resources, in the service group online.

Configuring a RemoteGroup resource

The RemoteGroup agent establishes dependencies between applications that are configured on different VCS clusters. With the RemoteGroup agent, you can monitor or manage a service group that exists in a remote cluster.

Some points about configuring the RemoteGroup resource are as follows:

- For each remote service group that you want to monitor or manage, you must configure a corresponding RemoteGroup resource in the local cluster.
- Multiple RemoteGroup resources in a local cluster can manage corresponding multiple remote service groups in different remote clusters.
- You can include the RemoteGroup resource in any kind of resource or service group dependency tree.
- A combination of the state of the local service group and the state of the remote service group determines the state of the RemoteGroup resource.

Before configuring the RemoteGroup resource, review the resource types, the attribute definitions, and the sample scenario described in the Veritas Cluster Server Bundled Agents Reference Guide.
**Configuration tasks**

1. In your service group, create resources of type IP and NIC. See “Adding a resource” on page 223 for instructions.

2. Create a resource of type RemoteGroup. See “Adding a RemoteGroup resource from the Java Console” on page 226 for instructions.

3. Configure the required attributes for the RemoteGroup resource. See the *Veritas Cluster Server Bundled Agents Reference Guide* for more information on the required attributes and their definitions.

4. Link the resources as follows:
   - Link the IP and NIC resources such that the IP resource depends on the NIC resource.
   - Link the RemoteGroup and NIC resources such that the RemoteGroup resource depends on the NIC resource. See “Linking resources” on page 236 for instructions.

5. Configure other resources in the service group, if required.

6. Bring the IP, NIC, and RemoteGroup resources online.
Configuring applications using the Application Configuration Wizard

VCS provides an Application Configuration Wizard to create service groups to monitor applications that are configured as resources of type GenericService, ServiceMonitor, or Process. You can also add registry replication, and network resources to application service groups using the wizard.

**Note:** The wizard does not configure the registry replication, and network resources independently. It configures these resources as part of a service group that has application resources.

On Windows Server 2008 Server Core, you have to add the required resources and configure the service group manually. You can perform the steps either directly on the Server Core machine using the vcs commands from the command line, or remotely using the Cluster Manager (Java console).

See “Administering the cluster from Cluster Manager (Java console)” on page 161.

See “Administering the cluster from the command line” on page 259.

Before configuring the service group, review the resource types and the attribute definitions of the agents described in the *Veritas Cluster Server Bundled Agents Reference Guide*.

Before you configure application service groups

Note the following prerequisites before you configure application service groups using the Application Configuration Wizard:

- Verify that the application you wish to configure is installed on all the nodes that are going to be part of the service group.

- Verify that the startup type of the application service that you wish to configure is set to manual on all the nodes that are going to be part of the service group.

- Verify that the application service is stopped on all the nodes that are going to be part of the service group.

- Verify that the shared drives or LUNs required by the applications are mounted on the node where you run the wizard.

See “Managing shared storage using Windows Logical Disk Manager” on page 309 for more information.

See for “Managing storage in a Network Appliance storage environment” on page 313 more information.
Configuring resources and applications in VCS

Configuring applications using the Application Configuration Wizard

See for “Managing shared storage using SFW” on page 315 more information.

■ If you have configured a firewall, add the following to the firewall exceptions list:
  ■ Port 14150 or the VCS Command Server service, %vcs_home%\bin\CmdServer.exe.
    Here, %vcs_home% is the installation directory for VCS, typically C:\Program Files\Veritas\Cluster Server.
  ■ Port 14141
    For a detailed list of services and ports used by SFW HA, refer to the Veritas Storage Foundation and High Availability Solutions for Windows Installation and Upgrade Guide.

■ Before running the wizard, make sure you have the following information ready:
  ■ Details of the application (application type, service name, start parameters, startup directory, etc.) that you wish to configure.
  ■ Shared storage required by the applications.
  ■ Application registry entries for configuring registry replication.
  ■ Network and virtual computer (Lanman) details for the application.

Note: These prerequisites apply to Application Configuration Wizard. For agent-specific prerequisites, see the agent descriptions in the Veritas Cluster Server Bundled Agents Reference Guide.

Adding resources to a service group

To add resources using the Application Configuration Wizard

1 Start the Application Configuration Wizard.
   Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Application Configuration Wizard.

2 Review the information in the Welcome panel and click Next.

3 In the Wizard Options panel, click Create service group and click Next.
4. On the Service Group Configuration panel, specify the service group details and then click **Next**. The wizard then starts validating your configuration. Various messages indicate the validation status.

5. The Application Options dialog box provides you the option to specify the type of application to be configured. The available options are:
   - **Generic Service**: Configures a service using the Generic Service agent. The agent brings services online, takes them offline, and monitors their status.
See “Configuring a GenericService resource” on page 393.

- Process: Configures a process using the Process agent. The agent brings processes online, takes them offline, and monitors their status. See “Configuring processes” on page 397.
- Service Monitor: Configures a service using the ServiceMonitor agent. The agent monitors a service or starts a user-defined script and interprets the exit code of the script. See “Configuring a ServiceMonitor resource” on page 401.

Configuring a GenericService resource

1. In the Application Options panel, click **Create**, select **GenericService** from the corresponding drop-down list, and click **Next**.
2 Select the service name for which you wish to configure a Generic Service resource. Also specify the attributes for the resource.

- Click the ellipsis button (…) adjacent to the Service Name text box and in the Services dialog box, select a service and click OK. The selected service appears in the Service Name text box.
- In the Start Parameters text box, provide the start parameters for the service, if any.
- In the Delay After Online text box, specify the number of seconds the agent waits after the service is brought online before starting the monitor routine.
- In the Delay After Offline text box, specify the number of seconds the agent waits after the service is taken offline before starting the monitor routine.
- Click Next.
3 Specify the information about the user in whose context the service will run.

- To configure a service to run in the context of a local system account, click **Local System account**.
- To configure a service to run in the context of another user account, click **This Account**. Specify the **Domain Name**, **User Name**, and **Password** for the user account.
- Click **Next**.
4 Select the shared storage required for the GenericService resource. The shared storage, which you select will be in addition to the mount where the service binaries exist.

- In the Available Shared Drives box, select the check box adjacent to the shared drive.
- Click **Next**.

5 In the Application Resource Summary panel, review the summary of the GenericService resource. Click **Back** to make changes. Otherwise, click **Next**.

6 The Application Options dialog box appears. Select one of the following options:

- To configure another GenericService resource, repeat step 1 through step 5.
- To configure a Process resource, proceed to “Configuring processes” on page 397 for instructions.
- To configure a ServiceMonitor resource, proceed to “Configuring a ServiceMonitor resource” on page 401 for instructions.
- To configure other resources, including FileShare, Registry Replication, and Network resources, proceed to “Configuring VCS components” on page 404 for instructions.

If you do not want to add any more resources to your service group, proceed to “Creating service groups” on page 408.
Configuring processes

1. In the Application Options panel, click **Create**, select **Process** from the corresponding list, and click **Next**.

2. Specify the details for the process.

   - In the Start Program text box, specify the complete path of the program that will start the process to be monitored by VCS. You can choose to
either type in the location of the program or browse for it using the ellipsis button (...).

- In the Start Program Parameters text box, specify the parameters used by the Process agent start program.

- In the Program Startup Directory text box, type the complete path of the Process agent program or browse for it by clicking the ellipsis button (...).

- In the Stop Program text box, type the complete path of the program that will stop the process started by the Start Program or browse for it by clicking the ellipsis button (...).

- In the Stop Program Parameters text box, specify the parameters used by the stop program.

- In the Monitor Program text box, type the complete path of the program that monitors the Start Program or browse for it by clicking the ellipsis button (...).

  If you do not specify a value for this attribute, VCS monitors the Start Program. If the Start Program is a script to launch another program, you must specify a monitor program.

- In the Monitor Program Parameters text box, specify the parameters used by the monitor program.

- In the Clean Program text box, type the complete path of the Clean process or browse for it by clicking the ellipsis button (...).

  If no value is specified, the agent kills the process indicated by the Start Program.

- In the Clean Program Parameters text box, specify the parameters used by the Clean program.

- Check the Process interacts with the desktop check box if you want the process to interact with your Windows desktop. Setting this option enables user intervention for the process.

- Click Next.
3 Specify information about the user in whose context the process will run.

- To configure a service to run in the context of a local system account, click **Local System account**.
- To configure a service to run in the context of another user account, click **This Account**. Specify the **Domain Name**, **User Name**, and **Password** for the user account.
- Click **Next**.
4 Select the shared storage required for the Process resource. The shared storage, which you select will be in addition to the mount where the service binaries exist.

- From the Available Shared Drives box, select the check box adjacent to the shared drive.
- Click Next.

5 In the Application Resource Summary panel, review the summary of the Process resource. Click Back to make changes. Otherwise, click Next.

6 The Application Options dialog box appears. Select one of the following options:
   - To configure another Process resource, repeat step 1 through step 5.
   - To configure a GenericService resource, see “Configuring a GenericService resource” on page 393 for instructions.
   - To configure a ServiceMonitor resource, proceed to “Configuring a ServiceMonitor resource” on page 401 for instructions.
   - To configure other resources, including FileShare, Registry Replication, and Network resources, proceed to “Configuring VCS components” on page 404 for instructions.

If you do not want to add any more resources to your service group, proceed to “Creating service groups” on page 408.
Configuring a ServiceMonitor resource

1. In the Application Options panel, click Create, select ServiceMonitor from the corresponding drop-down list, and click Next.

2. Specify the service to be monitored or a user-defined script to monitor a service.
If you want VCS to monitor the service:

- Select the **Service** option and click the the ellipsis button (...) adjacent to the Service Name text box.
- In the Service dialog box, select the service and click **OK**. The selected service name appears in the Service Name text box. Alternatively, You may also type in the service name to be monitored.
- Click **Next**.

If you want a script to monitor the service:

- Specify the complete path for the script using the ellipsis button (...).
- Specify the parameters for the script.
- Specify the time in seconds for the agent to receive a return value from the monitor script.
- Click **Next**.

3 Specify the user information in whose context the service will be monitored.

- To configure a service to run in the context of a local system account, click **Local System account**.
- To configure a service to run in the context of another user account, click **This Account**. Specify the **Domain Name**, **User Name**, and **Password** for the user account.
  
  If the service selected in step 2 on page 401 is running in the context of a local system account, the **This Account** option is disabled. Similarly, if
the service is running in the context of any other user account, the **Local System account** option is disabled.

- Click **Next**.

Service Monitor resource belongs to the category of persistent resources. Such resources do not depend on other VCS resources, including shared storage. Hence, the Shared Storage Option dialog box does not appear if you select the ServiceMonitor option.

4 In the Application Resource Summary panel, review the summary of the ServiceMonitor resource. Click **Back** to make changes. Otherwise, click **Next**.

5 The Application Options dialog box appears. Select one of the following options:

- To configure another ServiceMonitor resource, repeat step 1 through step 4.
- To configure a GenericService resource, see “Configuring a **GenericService resource**” on page 393 for instructions.
- To configure a Process resource, see “Configuring processes” on page 397 for instructions.
- To configure other resources, including FileShare, Registry Replication, and Network resources, proceed to “Configuring VCS components” on page 404 for instructions.

If you do not want to add any more resources to your service group, proceed to “Creating service groups” on page 408.
Configuring VCS components

Applications configured using GenericService or Process resources may require network components, or registry replication resources. You can configure these VCS components only for service groups created using the wizard.

**Note:** Configure these components only after configuring all application resources. The wizard creates a service group after these components are configured. To add more application resources, you must rerun the wizard in the Modify mode.

**To configure VCS components**

1. In the Application Options panel, click **Configure Other Components**.
2 Select the VCS component to be configured for your applications. The available options are as follows:

- Registry Replication Component: Select this option to configure registry replication for your application. To configure a Registry Replication resource, proceed to step 3 on page 406.

- Network Component: Select this option to configure network components for your application. If you wish to configure a virtual computer name, check **Lanman component** also. To configure a network resource, proceed to step 5 on page 407.

The wizard does not enable the **Lanman Component** check box unless the **Network Component** check box is checked.
To configure Registry Replication

3 Specify the registry keys to be replicated.

The RegistryReplication dialog box appears only if you chose to configure the Registry Replication Component in the Application Component dialog box.

- Specify the directory on the shared disk in which the registry changes are logged.
- Click Add.
- In the Registry Keys dialog box, select the registry key to be replicated.
- Click OK. The selected registry key is added to Registry KeyList box.
- Check the **Configure NetApp SnapMirror Resource(s)** check box if you wish to set up a disaster recovery configuration. This is applicable in case of VCS for Windows only. The SnapMirror resource is used to monitor replication between filers at the primary and the secondary site, in a disaster recovery configuration. Note that you must configure the SnapMirror resource only after you have configured the cluster at the secondary site.
- Click Next.

If you chose Network Component from the Application Component dialog box, proceed to the next step. Otherwise, proceed to step 6 on page 408.
To configure network components

4 This is applicable in case of VCS for Windows only.
   On the Initiator Selection panel, select the initiator for the virtual disk from
   the list of available initiators displayed for each cluster node, and then click
   Next.
   If you are configuring MPIO over FC, you must select at least two FC
   initiators for each cluster node. Note that the node from which you run this
   wizard already has an initiator selected by default. This is the initiator that
   was specified when you connected the LUNs to this cluster node.

5 Specify information related to your network.
   The Virtual Computer Configuration dialog box appears only if you chose to
   configure the Network Component in the Application Component dialog
   box.
   ■ Enter a unique virtual computer name by which the node will be visible
      to the other nodes. Note that the virtual name must not exceed 15
      characters.
      Note that the Virtual Computer Name text box is displayed only if you
      chose to configure the Lanman Component in Application Component
      dialog box.
   ■ Enter a unique virtual IP address for the virtual server.
   ■ Enter the subnet to which the virtual server belongs.
   ■ Click Advanced to specify additional details for the Lanman resource.
      ■ Check AD Update required to enable the Lanman resource to
         update the Active Directory with the virtual name. This sets the
         Lanman agent attributes ADUpdateRequired and
         ADCriticalForOnline to true.
      ■ In the Organizational Unit field type the distinguished name of the
         Organizational Unit for the virtual server in the format
         CN=containername,DC=domainname,DC=com. To browse for an
         OU, click the ellipsis (...) button and search for the OU using the
         Windows Find Organization Units dialog box for the virtual server.
         By default, the Lanman resource adds the virtual server to the
         default container "Computers."
         The user account for VCS Helper service must have adequate
         privileges on the specified container to create and update
         computer accounts.
      ■ Click OK.
   ■ For each system in the cluster, select the public network adapter name.
      To view the adapters associated with a system, click the Adapter
      Display Name field and click the arrow.
Note that the wizard displays all TCP/IP enabled adapters on a system, including the private network adapters, if applicable. Verify that you select the adapters assigned to the public network, not the private.

- Click **Next**.

6 The Application Options dialog box is displayed. Select one of the following options:

- To configure additional VCS components, repeat step 1 on page 404 through step 5 on page 407.
- To configure a GenericService resource, see “Configuring a GenericService resource” on page 393 for instructions.
- To configure a Process resource, see “Configuring processes” on page 397 for instructions.
- To configure a Service Monitor resource, see “Configuring a ServiceMonitor resource” on page 401 for instructions.

If you do not want to add any more resources to your service group, proceed to “Creating service groups” on page 408.

### Creating service groups

The Application Configuration Wizard enables you to create service group for the application resources and other VCS components configured using the wizard. This section describes how to create the service group using the wizard.
To create a service group

1. In the Application Options panel, click **Configure application dependency and create service group**.

   ![Application Configuration Wizard](image)

   The option is enabled only if:
   - resources and VCS components are already configured using the wizard.
   - you clicked **Modify Service Groups** in the Wizard Options panel.
2 Specify the dependency between the applications.

You must have at least two resources configured for this dialog box to appear. Of the two resources, one should either be a GenericService or a Process resource.

- From the Select Application list, select the application that would depend on other applications. The selected application becomes the parent application.
- From the Available Applications list, select the application on which the parent application would depend and click the right-arrow icon to move the application to the Child Applications list.
  To remove an application from the Child Applications list, select the application in the list and click the left arrow.
Repeat these steps for all such applications for which you want to create a dependency.
- Click Next.

The Application Dependency dialog box enables you to link resources configured using the wizard. If these resources are dependent on other services outside the VCS environment, you should first configure resources for such services and then create the appropriate dependency.
3 Review the service group configuration.

The Resources box lists the configured resources. Click on a resource to view its attributes and their configured values in the Attributes box.

- The wizard assigns unique names to resources. Change names of resource, if required.
  To edit a resource name, select the resource name and either click it or press the F2 key. Press Enter after editing each resource name. To cancel editing a resource name, press the Esc key.

- Click **Next**.

- A message appears informing you that the wizard will run commands to modify the service group configuration. Click **Yes**.
  The wizard starts running commands to create the service group. Various messages indicate the status of these commands. After the commands are executed, the completion dialog box appears.

4 In the completion panel, check **Bring the service group online** if you want to bring the service group online on the local system.

5 Click **Finish** to create the service group and exit the Application Configuration Wizard.
Modifying an application service group

This section describes how to modify a service group using the Application Configuration Wizard.

- If the service group to be modified is online, you must run the wizard from a system on which the service group is online. You can then add and remove resources to the configuration using the wizard; you cannot modify resources that are online.

- To change the online resource attributes, you must take the service group offline. However, the MountV and VMDg (in case of SFW HA), Mount and DiskRes (in case of Windows LDM) and NetAppSnapDrive and NetAppFiler (in case of VCS for Windows) resources for the service group should be online on the node where you run the wizard and offline on all other nodes.

- If you are running the wizard to remove a node from the service group's system list, do not run the wizard on the node being removed.

- If the service group contains resources that were not part of the default service group configuration, then modifying the service group may change those resources. You may then have to manually restore the settings of those resources later.

Note: Symantec recommends that you do not use the wizard to modify service groups that were not created using the wizard.

To modify a service group using the wizard

1. Start the Application Configuration Wizard.
   Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Application Configuration Wizard.

2. Review the information in the Welcome panel and click Next.

3. In the Wizard Options panel, click Modify service group. From the Service Groups list, select the service group containing the resource that you want to modify and click Next.

4. In the Service Group Configuration panel, click Next.
5 Click Modify, select the resource you want to modify and then click Next.

![Application Configuration Wizard](image)

The Modify option is enabled only if:
- Service and Process resources are already configured using the wizard.
- You selected the Modify Service Groups option in the Wizard Options panel.

6 Depending on the resource you chose to modify from the Application Options page, you would either get the Generic Service Options (see “Configuring a GenericService resource” on page 393), Process Details (see “Configuring processes” on page 397), or Service Monitor Options dialog box (see “Configuring a ServiceMonitor resource” on page 401). Make required changes in the appropriate dialog box and click Next.

7 In the User Details dialog box, specify the user information and click Next.

8 In the Application Resource Summary dialog box, review the summary of the resource. Click Back to make changes. Otherwise, click Next.

9 The Application Options dialog box appears. Repeat step 5 through step 8 for each resource that you want to modify.
10 After modifying the required resources, you can:

- Add additional resources to the service group.
  See “Adding resources to a service group” on page 391 for instructions.

- Delete resources from the service group.
  See “Deleting resources from a service group” on page 415 for instructions.

- Add VCS components to the service group.
  See “Configuring VCS components” on page 404 for instructions.

- Create the service group.
  See “Creating service groups” on page 408 for instructions.
Deleting resources from a service group

This section describes how to delete a resource within a service group using the Application Configuration Wizard.

To delete a resource

1. Start the Application Configuration Wizard.
   Click Start > All Programs > Symantec Cluster Server > Configuration Tools > Application Configuration Wizard.

2. Read the text on the Welcome panel and click Next.

3. In the Wizard Options panel, click Modify Service Group. From the Service Groups list, select the service group containing the resource that you want to delete and click Next.

4. In the Service Group Configuration panel, click Next.

5. In the Application Options panel, click Delete, select the resource you want to delete, and click Next.

6. In the Warning dialog box, click No to retain the selected resource. Otherwise, click Yes.
   The specified resource will be deleted when you exit the wizard after selecting the Configure application dependency and create service group option in the Application Options panel.

7. After marking the resource for deletion, you can:
   - Add additional resources to the service group.
     See “Adding resources to a service group” on page 391 for instructions.
   - Modify resources in the service group.
     See “Modifying an application service group” on page 412 for instructions.
   - Add VCS components to the service group.
     See “Configuring VCS components” on page 404 for instructions.
   - Create the service group.
     See “Creating service groups” on page 408 for instructions.
Deleting an application service group

This section describes steps to delete an application service group using the configuration wizard.

To delete a service group using the wizard

1. Start the Application Configuration Wizard on a system configured to host the application service group.
   Click Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Application Configuration Wizard.

2. Review the information in the Welcome panel and click Next.

3. In the Wizard Options panel, click Delete service group, select the service group to be deleted, and click Next.

4. In the Service Group Summary panel, click Next.

5. A message appears informing you that the wizard will run commands to delete the service group. Click Yes to delete the service group.

6. Click Finish.
About the VCS Application Manager utility

VCS starts application services under the context of the respective virtual server configured in the cluster. As the Windows MMC snap-in is not aware of the virtual server configuration, it is not possible to manage the application from the MMC snap-in.

VCS provides a utility, VCS Application Manager (VAM), that allows you to manage applications in the virtual server context. You can use VAM to launch application management tools and system management tools in the virtual server context.

VAM supports the following applications:
- Microsoft Exchange Server 2007
- Microsoft Distributed Transaction Coordinator (MSDTC)
- Microsoft Message Queing (MSMQ)

Managing applications in virtual server context

Use the following steps to start application management tools in the virtual server context using the VCS Application Manager utility.

Before you proceed, ensure that the virtual server resource (Lanman resource) configured in the application service group is online on the node where you run the VAM utility.

To manage applications in virtual server context

1. Start the VCS Application Manager utility.
   Click Start > Programs > Symantec > Veritas Cluster Server > Configuration Tools > Application Manager.
   Or
   In the Solutions Configuration Center (SCC), under Tools, click VCS Application Manager.
   The VCS Application Manager displays a list of supported application service groups configured in the cluster. For each service group it also displays the state of the service group, the name of the virtual server resource (Lanman resource) and the corresponding management tools used for that application.

2. If you wish to sort applications based on their resource type, select the desired resource type from the Select the resource type drop-down list. The following resource types are available for selection:
   - ExchService2007
   - MSDTC
- **MSMQ**

3 Select an application resource that is online and then click **Manage**, or double-click the resource name.

VAM launches the management tool in the virtual server context. You can then perform the desired tasks from the management tool.

For example, if you have selected an MSDTC resource, the Computer Services snap-in is launched. You can view the distributed transactions on the virtual DTC server.

To launch a different management tool than the one displayed, click the tool name in the Managed Application column and then select the available tool from the drop-down list.

Table 9-3 displays the supported applications and the respective management tools that are available.

### Table 9-4  VAM: applications and tools available

<table>
<thead>
<tr>
<th>Application (Resource type)</th>
<th>Management tools available</th>

</thead>
</table>
| Exchange Server 2007 (ExchService2007) | Exchange Management Shell  
You can launch the Exchange Management Shell and run cmdlets to perform various administrative tasks on the configured Exchange server. |
| Microsoft Distributed Transaction Coordinator (MSDTC) | Component Services  
You can view the distributed transactions statistics on the DTC virtual server from a node where the MSDTC resource is online. |
| Microsoft Message Queuing (MSMQ) | Computer Management, Performance Counters  
You can manage MSMQ message queues on the node where the MSMQ resource is online. |
Testing resource failover using virtual fire drills

Configuring high availability for a database or an application requires several infrastructure and configuration settings on multiple systems. However, cluster environments are subject to change after the initial setup. Administrators add disks, create new diskgroups and volumes, add new cluster nodes, or new NICs to upgrade and maintain the infrastructure. Keeping the cluster configuration updated with the changing infrastructure is critical.

Virtual fire drills detect discrepancies between the VCS configuration and the underlying infrastructure on a node; discrepancies that might prevent a service group from going online on a specific node.

About virtual fire drills

The virtual fire drill feature uses the Action entry point associated with the agent. The Action entry points of the supported agents are updated to support the virtual fire drill functionality—running infrastructure checks and fixing specific errors.

The infrastructure check verifies the resources defined in the VCS configuration file (main.cf) have the required infrastructure to fail over on another node. For example, an infrastructure check for the MountV resource verifies the existence of the mount point (drive letter) defined in the MountPath attribute for the resource.

You can run an infrastructure check only when the service group is online. The check verifies that the specified node is a viable failover target capable of hosting the service group.

The virtual fire drill provides an option to fix specific errors detected during the infrastructure check.

Infrastructure checks and fixes for supported agents

Running a virtual fire drill

You can run a virtual fire drill from the command line or from Cluster Manager (Java Console).

See "Running HA fire drill from the Java Console" on page 241.
Modifying the cluster configuration

- About modifying the cluster configuration
- Adding nodes to a cluster
- Removing nodes from a cluster
- Reconfiguring a cluster
- Enabling and disabling Symantec Product Authentication Service
- Configuring the ClusterService group
- Deleting a cluster configuration
About modifying the cluster configuration

This chapter describes how to modify and delete a cluster configuration using the VCS Configuration wizard. The chapter also describes how to enable and disable Veritas Security Services in clusters configured to run in secure mode.

Use the VCS Configuration Wizard (VCW) to modify and delete a cluster configuration. When used to modify a cluster configuration, the wizard performs the following tasks:

- Adds nodes to a cluster
- Remove nodes from a cluster
- Reconfigures the private network and LLT
- Reconfigures Veritas Security Services
- Configures the ClusterService service group in the cluster

When used to delete a cluster configuration, the wizard removes the cluster components from the nodes; the wizard does not uninstall VCS.
Adding nodes to a cluster

Before adding a node to a cluster, install VCS on the node:

- If you purchased VCS for Windows, refer to the *Veritas Cluster Server for Windows Installation and Upgrade Guide*.
- If you purchased Storage Foundation for Windows High Availability, refer to the *Veritas Storage Foundation and High Availability Solutions Installation and Upgrade Guide*.

The VCS Cluster Configuration Wizard (VCW) configures VCS components and starts VCS services on the new node. The wizard does not configure any service groups on the new node.

**Note:** To add nodes to single node cluster without private link heartbeat configured, you must first reconfigure the cluster to include the private links. See “Reconfiguring a cluster” on page 434.

**To add a node to a VCS cluster**

1. Start the VCS Cluster Configuration wizard.
   
   Click **Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Cluster Configuration Wizard**.

   Run the wizard from the node to be added or from a node in the cluster. The node that is being added should be part of the domain to which the cluster belongs.

2. Read the information on the Welcome panel and click **Next**.

3. On the Configuration Options panel, click **Cluster Operations** and click **Next**.
4  In the Domain Selection panel, select or type the name of the domain in which the cluster resides and select the discovery options.

Do one of the following:

■ To discover information about all the systems and users in the domain:
  ■ Clear the **Specify systems and users manually** check box.
  ■ Click **Next**.
  
  Proceed to step 8 on page 427.

■ To specify systems and user names manually (recommended for large domains):
  ■ Check the **Specify systems and users manually** check box.
  
  Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.
  ■ Click **Next**.
  
  If you chose to retrieve the list of systems, proceed to step 6 on page 426. Otherwise proceed to the next step.
On the System Selection panel, complete the following and click **Next**.

- Type the name of a node in the cluster and click **Add**.
- Type the name of the system to be added to the cluster and click **Add**.

If you specify only one node of an existing cluster, the wizard discovers all nodes for that cluster. To add a node to an existing cluster, you must specify a minimum of two nodes; one that is already a part of a cluster and the other that is to be added to the cluster.

Proceed to step 8 on page 427.
6 On the System Selection panel, specify the systems to be added and the nodes for the cluster to which you are adding the systems.

Enter the system name and click Add to add the system to the Selected Systems list. Alternatively, you can select the systems from the Domain Systems list and click the right-arrow icon.

If you specify only one node of an existing cluster, the wizard discovers all nodes for that cluster. To add a node to an existing cluster, you must specify a minimum of two nodes; one that is already a part of a cluster and the other that is to be added to the cluster.

7 The System Report panel displays the validation status, whether Accepted or Rejected, of all the systems you specified earlier. Review the status and then click Next.

A system can be rejected for any of the following reasons:

- System is not pingable.
- WMI access is disabled on the system.
- Wizard is unable to retrieve the system architecture or operating system.
- VCS is either not installed on the system or the version of VCS is different from what is installed on the system on which you are running the wizard.

Click on a system name to see the validation details. If you wish to include a rejected system, rectify the error based on the reason for rejection and then run the wizard again.
8 On the Cluster Configuration Options panel, click **Edit Existing Cluster** and click **Next**.

9 On the Cluster Selection panel, select the cluster to be edited and click **Next**. If you chose to specify the systems manually in step 4, only the clusters configured with the specified systems are displayed.

10 On the Edit Cluster Options panel, click **Add Nodes** and click **Next**. In the Cluster User Information dialog box, type the user name and password for a user with administrative privileges to the cluster and click **OK**.

The Cluster User Information dialog box appears only when you add a node to a cluster with VCS user privileges, that is when the cluster configuration does not use the Symantec Product Authentication Service for secure cluster communication.

11 On the Cluster Details panel, check the check boxes next to the systems to be added to the cluster and click **Next**.

The right pane lists nodes that are part of the cluster. The left pane lists systems that can be added to the cluster.

12 The wizard validates the selected systems for cluster membership. After the nodes have been validated, click **Next**. If a node does not get validated, review the message associated with the failure and restart the wizard after rectifying the problem.

13 On the Private Network Configuration panel, configure the VCS private network communication on each system being added and then click **Next**. How you configure the VCS private network communication depends on
how it is configured in the cluster. If LLT is configured over ethernet, you have to use the same on the nodes being added. Similarly, if LLT is configured over UDP in the cluster, you have use the same on the nodes being added.

Do one of the following:

- To configure the VCS private network over ethernet, complete the following steps:
  - Select the check boxes next to the two NICs to be assigned to the private network. Symantec recommends reserving two NICs exclusively for the private network. However, you could lower the priority of one NIC and use the low-priority NIC for both public and private communication.
  - If you have only two NICs on a selected system, it is recommended that you lower the priority of at least one NIC that will be used for private as well as public network communication. To lower the priority of a NIC, right-click the NIC and select **Low Priority** from the pop-up menu.
  - If your configuration contains teamed NICs, the wizard groups them as "NIC Group #N" where "N" is a number assigned to the teamed NIC. A teamed NIC is a logical NIC, formed by grouping several physical NICs together. All NICs in a team have an identical MAC address. Symantec recommends that you do not select teamed NICs for the private network.

The wizard will configure the LLT service (over ethernet) on the selected network adapters.

- To configure the VCS private network over the User Datagram Protocol (UDP) layer, complete the following steps:
  - Check the **Configure LLT over UDP** check box.
  - Specify a unique UDP port in the **Port number for Link1** and **Port number for Link2** fields. You can use ports in the range 49152 to 65535. The default ports numbers are 50000 and 50001 respectively.
  - Select the check boxes next to the two NICs to be assigned to the private network. Symantec recommends reserving two NICs exclusively for the VCS private network.
  - For each selected NIC, verify the displayed IP address. If a selected NIC has multiple IP addresses assigned, double-click the field and choose the desired IP address from the drop-down list. Each IP address can be in a different subnet.
The IP address is used for the VCS private communication over the specified UDP port.

For each selected NIC, double-click the respective field in the Link column and choose a link from the drop-down list. Specify a different link (Link1 or Link2) for each NIC. Each link is associated with a UDP port that you specified earlier.

The wizard will configure the LLT service (over UDP) on the selected network adapters. The specified UDP ports will be used for the private network communication.

14 On the Public Network Communication panel, select a NIC for public network communication, for each system that is being added, and then click Next.

This step is applicable only if you have configured the ClusterService service group, and the system being added has multiple adapters. If the system has only one adapter for public network communication, the wizard configures that adapter automatically.

15 Specify the password for the user in whose context the VCS Helper service runs.

16 Review the summary information and click Add.

17 The wizard starts running commands to add the node. After all commands have been successfully run, click Finish.
Removing nodes from a cluster

The following steps describe how to remove nodes from a multiple node VCS cluster. To remove a node from a single node cluster, you must delete the cluster.

See “Deleting a cluster configuration” on page 454 for instructions.

To remove nodes from a cluster

1. Verify no service groups are online on the node to be removed.
2. Remove the node from the SystemList of all service groups.
3. Start the VCS Configuration wizard. Click **Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Cluster Configuration Wizard**.
4. Read the information on the Welcome panel and click **Next**.
5. In the Configuration Options panel, click **Cluster Operations** option and click **Next**.
6. In the Domain Selection panel, select or type the name of the domain in which the cluster resides and select the domain discovery options.

Do one of the following:

- To discover information about all the systems and users in the domain
  - Uncheck the **Specify systems and users manually** check box.
  - Click **Next**.
  - Proceed to step 10 on page 432.
To specify systems and user names manually (recommended for large domains):

- Check the **Specify systems and users manually** check box. Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.

- Click **Next**. If you checked **Retrieve system list from domain**, proceed to step 8 on page 432. Otherwise proceed to the next step.

7 In the System Selection panel, type the name of the system and click **Add**.

Proceed to step 10 on page 432.
8 In the System Selection panel, specify the systems for the cluster from which you will be removing the nodes.

Enter the system name and click Add to add the system to the Selected Systems list. Alternatively, you can select the systems from the Domain Systems list and click the right-arrow icon. If you specify only one node of an existing cluster, the wizard discovers all nodes for that cluster.

9 The System Report panel displays the validation status, whether Accepted or Rejected, of all the systems you specified earlier. Review the status and click Next.

A system can be rejected for any of the following reasons:

- System is not pingable.
- WMI access is disabled on the system.
- Wizard is unable to retrieve the system architecture or operating system.
- VCS is either not installed on the system or the version of VCS is different from what is installed on the system on which you are running the wizard.

Click on a system name to see the validation details. If you wish to include a rejected system, rectify the error based on the reason for rejection and then run the wizard again.

10 In the Cluster Configuration Options panel, click Edit Existing Cluster and then click Next.

11 In the Cluster Selection panel, select the cluster to be edited and click Next.
If you chose to specify the systems manually in step 6 on page 430, only the clusters configured with the specified systems are displayed.

12 In the Edit Cluster Options panel, click Remove Nodes and then click Next. In the Cluster User Information panel, enter the user name and password for a user with administrative privileges to the cluster and click OK. The Cluster User Information dialog box appears only when you remove a node from a non-secure cluster.

13 In the Cluster Details panel, select the check boxes next to the nodes to be removed and click Next. The wizard does not remove a root broker node from a secure cluster. To remove a root broker node, you must reconfigure the cluster to have a different root broker. See “Reconfiguring a cluster” on page 434 for instructions.

14 If you want to remove the VCS Helper Service user account from the administrative group of the nodes being removed from the cluster, click Yes from the informational dialog box. Otherwise, click No.

15 The wizard validates the selected nodes. After the nodes have been validated, click Next. If a node does not get validated, review the message associated with the failure and restart the wizard after rectifying the problem.

An informational dialog box appears if you are removing all but one nodes of a multiple node cluster. In the dialog box, specify whether you want to retain or remove the private link heartbeat.

16 Review the summary information and click Remove.

17 The wizard starts running commands to remove the node from the cluster. After the commands have been successfully run, click Finish.
Reconfiguring a cluster

You might need to reconfigure your cluster after changing an adapter on a cluster node, to update the LLT information, or to configure Veritas Security Services.

To reconfigure a cluster

2. Read the information on the Welcome panel and click Next.
3. In the Configuration Options panel, click Cluster Operations and click Next.
4. In the Domain Selection panel, select or type the name of the domain in which the cluster resides and click Next.

Do one of the following:

- To discover information about all the systems and users in the domain
  - Uncheck the Specify systems and users manually check box.
  - Click Next.
  - Proceed to step 8 on page 436.
- To specify systems and user names manually (recommended for large domains)
  - Check the Specify systems and users manually check box.
Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.

- Click Next.

If you checked **Retrieve system list from domain**, proceed to step 6 on page 436. Otherwise proceed to the next step.

5 In the System Selection panel, type the name of the system and click **Add**.

Proceed to step 8 on page 436.
In the System Selection panel, specify the systems for the cluster to be reconfigured.

Enter the system name and click **Add** to add the system to the Selected Systems list. Alternatively, you can select the systems from the Domain Systems list and click the right-arrow icon.

If you specify only one node of an existing cluster, the wizard discovers all nodes for that cluster.

The System Report panel displays the validation status, whether **Accepted** or **Rejected**, of all the systems you specified earlier. Review the status and click **Next**.

A system can be rejected for any of the following reasons:

- System is not pingable.
- WMI access is disabled on the system.
- Wizard is unable to retrieve the system architecture or operating system.
- VCS is either not installed on the system or the version of VCS is different from what is installed on the system on which you are running the wizard.

Click on a system name to see the validation details. If you wish to include a rejected system, rectify the error based on the reason for rejection and then run the wizard again.

In the Cluster Configuration Options panel, click **Edit Existing Cluster** and click **Next**.
9 In the Cluster Selection panel, select the cluster to be reconfigured and click **Next**. If you chose to specify the systems manually in **step 4 on page 434**, only the clusters configured with the specified systems are displayed.

10 In the Edit Cluster Options panel, click **Reconfigure** and click **Next**.
   In the Cluster User Information dialog box, enter the user name and password for a user with administrative privileges to the cluster and click **OK**.
   The Cluster User Information dialog box appears only when you reconfigure a non-secure cluster.

11 In the second Edit Cluster Options dialog box, select any of the following options:
   - **Change private network heartbeat links**
     Select this option to change the private network heartbeat links.
     If the selected cluster is a single node cluster, the option is to remove the private heartbeat links.
     If the cluster has more than one node, the options are to add or remove private heartbeat links.
     See **step 12 on page 437**.
   - **Change HAD Helper User account**
     Selection this options to change the user account for the Veritas Cluster Server Helper service.
     See **step 13 on page 440**.
   - **Configure/Change Veritas Security Services**
     Select this option to configure or change Veritas Security Services for single sign-on, or to add or change the root broker.
     See **step 14 on page 440**.

12 If the option to change the private network heartbeat links was selected, do one of the following:
To configure the VCS private network over ethernet, complete the following steps:

- Select the check boxes next to the two NICs to be assigned to the private network. Symantec recommends reserving two NICs exclusively for the private network. However, you could lower the priority of one NIC and use the low-priority NIC for public and private communication.

- If you have only two NICs on a selected system, it is recommended that you lower the priority of at least one NIC that will be used for private as well as public network communication. To lower the priority of a NIC, right-click the NIC and select **Low Priority** from the pop-up menu.

- If your configuration contains teamed NICs, the wizard groups them as "NIC Group #N" where "N" is a number assigned to the teamed NIC. A teamed NIC is a logical NIC, formed by grouping several physical NICs together. All NICs in a team have an identical MAC address. Symantec recommends that you do not select teamed NICs for the private network. The wizard will configure the LLT service (over Ethernet) on the selected network adapters.
To configure the VCS private network over the User Datagram Protocol (UDP) layer, complete the following steps:

- Check the **Configure LLT over UDP** check box.
- Specify a unique UDP port in the **Port number for Link1** and **Port number for Link2** fields. You can use ports in the range 49152 to 65535. The default ports numbers are 50000 and 50001 respectively.
- Select the check boxes next to the two NICs to be assigned to the private network. Symantec recommends reserving two NICs exclusively for the VCS private network.
- For each selected NIC, verify the displayed IP address. If a selected NIC has multiple IP addresses assigned, double-click the field and choose the desired IP address from the drop-down list. Each IP address can be in a different subnet. The IP address is used for the VCS private communication over the specified UDP port.
- For each selected NIC, double-click the respective field in the Link column and choose a link from the drop-down list. Specify a different link (Link1 or Link2) for each NIC. Each link is associated with a UDP port that you specified earlier. The wizard will configure the LLT service (over UDP) on the selected network adapters. The specified UDP ports will be used for the private network communication.
13 If the option to change the VCS HAD Helper User account was selected, in the VCS Helper Service User Account dialog box, specify the name of a domain user in whose context the VCS Helper service will run.

The VCS High Availability Daemon, which runs in the context of the local system built-in account, uses the VCS Helper Service user context to access the network.

- Select one of the following
  - **Existing user**
    Choose an existing user account context for the VCS Helper service.
  - **New user**
    Create a new user account context for the VCS Helper service.
  - **Configured users**
    If multiple user accounts are configured on different cluster nodes, this option appears. Select one of the user accounts to configure. This account will then be configured on all the cluster nodes.

- Enter a valid user name for the selected account and click **Next**. Do not append the domain name to the user name; do not enter user names as Domain\user or user@Domain.

- Enter a password for the selected account and click **OK**.

14 If the option to change Symantec Product Authentication Service was selected, specify security settings for the cluster.
The wizard enables you to configure Symantec Product Authentication Service. If it is already configured, the wizard enables you to change the root broker.

- To configure Symantec Product Authentication Service in the cluster, do the following:
  - Click **Use Single Sign-on**. In this mode, VCS uses SSL encryption and platform-based authentication. The VCS engine (HAD) and Veritas Command Server run in secure mode.
    For more information about secure communications in a cluster, see the *Veritas Storage Foundation and High Availability Solutions Quick Start Guide for Symantec Product Authentication Service*.
  - To specify or change the root broker: If you know the name of the system that will serve as the root broker, click **Specify an existing root broker or a node in this cluster to configure as root broker**, type the system name, and then click **Next**.
    If you specify a cluster node, the wizard configures the node as the root broker and other nodes as authentication brokers. Authentication brokers reside one level below the root broker and serve as intermediate registration and certification authorities. These brokers can authenticate clients, such as users or services, but cannot authenticate other brokers. Authentication brokers have certificates signed by the root.
    If you specify a system outside of the cluster, make sure that the system is configured as a root broker; the wizard then configures all nodes in the cluster as authentication brokers.
  - If you want to search the system that will serve as root broker, click **Discover the root broker systems in the domain** and click **Next**. The wizard will discover root brokers in the entire domain, by default.
  - If you want to define a search criteria, click **Scope**. In the Scope of Discovery dialog box, click **Entire Domain** to search across the domain, or click **Specify Scope** and select the Organization Unit from the Available Organizational Units list, to limit the search to the specified organization unit. Use the Filter Criteria options to search systems matching a certain condition.
    For example, to search for systems managed by a user *Administrator*, select **Managed by** from the first drop-down list, **is (exactly)** from the second drop-down list, type the user name *Administrator* in the adjacent field, click **Add**, and then click **OK**.
Table 10-1 on page 442 contains some more examples of search criteria.

<table>
<thead>
<tr>
<th>1st drop-down list value</th>
<th>2nd drop-down list value</th>
<th>Adjacent field entry</th>
<th>Search result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>is (exactly)</td>
<td>*system</td>
<td>Displays all systems with names that end with <em>system</em>.</td>
</tr>
<tr>
<td>Name</td>
<td>is (exactly)</td>
<td><em>vcsnode</em></td>
<td>Displays all systems with names that contain <em>vcsnode</em>.</td>
</tr>
<tr>
<td>Operating System</td>
<td>is (exactly)</td>
<td>'2003'</td>
<td>Displays all Windows Server 2003 systems.</td>
</tr>
<tr>
<td>Operating System</td>
<td>is (exactly)</td>
<td>'Enterprise'</td>
<td>Displays all Windows Server 2003 Enterprise Edition systems.</td>
</tr>
<tr>
<td>Operating System Version</td>
<td>is (exactly)</td>
<td>5.*</td>
<td>Displays all systems whose operating system version is 5.x, where x could be 0, 1, 2, etc.</td>
</tr>
</tbody>
</table>

You can add multiple search criterion; the wizard will search for systems that match all the conditions specified.

- Click Next. The wizard discovers and displays a list of all the root brokers. Click to select a system that will serve as the root broker and then click Next.
  
  If the root broker is a cluster node, the wizard configures the other cluster nodes as authentication brokers. If the root broker is outside the cluster, the wizard configures all the cluster nodes as authentication brokers.

15  Review the summary information and click Reconfigure.

16  The wizard starts running commands to apply the changes. After all services have been successfully configured, click Finish.
Enabling and disabling Symantec Product Authentication Service

This section describes how to enable and disable Symantec Product Authentication Service for clusters running in secure mode. Note that these procedures apply only if you have configured Symantec Product Authentication Service in the cluster.

For instructions on how to configure Symantec Product Authentication Service in a cluster, see “Reconfiguring a cluster” on page 434.

To enable Symantec Product Authentication Service

1. Stop VCS on all nodes:
   ```
   C:\> hastop -all
   ```

2. Stop the Veritas Command Server service on all nodes.

3. On each node in the cluster, create an empty file with the name `.secure` under `%VCS_HOME%\conf\config`, where `%VCS_HOME%` represents the VCS installation directory, typically `C:\Program Files\Veritas\Cluster Server`.

4. Start the Veritas Command Server service on all nodes.

5. Set the SecureClus attribute to 1 in your configuration file main.cf. Open the configuration file main.cf using Notepad, and add the following line in the cluster definition:

   ```
   SecureClus = 1
   ```

   For example:

   ```
   cluster VCSCluster9495 {
     UserNames = { admin = gmnFmhMjnInnLvHmk }
     Administrators = { admin }
     SecureClus = 1
     CredRenewFrequency = 0
     CounterInterval = 5
   }
   ```

6. Save the configuration.

7. Start the VCS engine on the local node:
   ```
   C:\> hastart
   ```

8. Start VCS on other nodes in the cluster.
To disable Symantec Product Authentication Service

1. Stop VCS on all nodes:
   C:/> hastop -all
2. Stop the Veritas Command Server service on all nodes.
3. From each node in the cluster, remove the .secure file from
   %VCS_HOME%/conf/config, where %VCS_HOME% represents the VCS
   installation directory, typically C:\Program Files\Veritas\Cluster
   Server.
4. Type the following on the command prompt:
   C:/> cmdserver -withoutsecurity
5. Start the Veritas Command Server service on all the nodes, if the service has
   not started.
6. Set the SecureClus attribute to 0 in your configuration file main.cf.
   Open the configuration file main.cf using Notepad, and add the following
   line in the cluster definition:
   SecureClus = 0
   For example:
   
   cluster VCSCluster9495 {
      UserNames = { admin = gmnFmhMjnInnLvnHmk }
      Administrators = { admin }
      SecureClus = 0
      CredRenewFrequency = 0
      CounterInterval = 5
   }
7. Save the configuration.
8. Start the VCS engine on the local node:
   C:\> hastart
9. Start VCS on other nodes in the cluster
Configuring the ClusterService group

Use the VCS Configuration wizard to configure the following ClusterService service group components, if you did not configure them during the initial cluster configuration:

■ Cluster Management Console (Single Cluster Mode) or Web Console
■ Notification
■ Inter-cluster communication for global clusters

Note that the wizard allows you to configure each component only once.

To configure the ClusterService group

2. Read the information on the Welcome panel and click Next.
3. In the Configuration Options panel, click Cluster Operations and click Next.
4. In the Domain Selection panel, select or type the name of the domain in which the cluster resides and click Next.

Do one of the following:

■ To discover information about all the systems and users in the domain
  ■ Uncheck the Specify systems and users manually check box.
  ■ Click Next.
Proceed to step 7 on page 447.

- To specify systems and user names manually (recommended for large domains)
  - Check the Specify systems and users manually check box. Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.
  - Click **Next**.
    If you checked the Retrieve system list from domain check box, proceed to step 6 on page 447. Otherwise proceed to the next step.

5. In the System Selection panel, type the name of the system and click **Add**.

![System Selection Panel](image)

Proceed to step 7 on page 447.
6 In the System Selection panel, specify the systems for the cluster where you will be configuring the ClusterService group.

Enter the system name and click **Add** to add the system to the Selected Systems list. Alternatively, you can select the systems from the Domain Systems list and click the right-arrow icon.

If you specify only one node of an existing cluster, the wizard will discover all the nodes for that cluster.

7 In the Cluster Configuration Options panel, click **Edit Existing Cluster** and then click **Next**.

8 In the Cluster Selection panel, select the cluster to be edited and click **Next**. If you chose to specify the systems manually in step 4, only the clusters configured with the specified systems are displayed.

9 In the Edit Cluster Options panel, click **Configure ClusterService Options** and then click **Next**.

In the Cluster User Information dialog box, enter the user name and password for a user with administrative privileges to the cluster and click **OK**.

The Cluster User Information dialog box appears only when you configure a ClusterService group in a non-secure cluster.

10 In the Cluster Service Components panel, select the components to be configured in the ClusterService service group.

- Check the **Web Console** check box to configure Cluster Management Console (Single Cluster Mode) also referred to as Web Console. See “Configuring Web Console” on page 448 for instructions.
Check the **Notifier Option** check box to configure notification of important events to designated recipients. See “Configuring notification” on page 449 for instructions.

Check the **GCO Option** check box to configure the wide-area connector (WAC) process for global clusters. The WAC process is required for inter-cluster communication. See “Configuring the wide-area connector process for global clusters” on page 453 for instructions.

Click **Next**.

### Configuring Web Console
Steps to configure the Web Console.

**To configure Web Console**

1. On the Web Console Network Selection panel, specify the network information for the Web Console resources and click **Next**.

   ![Web Console Network Selection panel](image)

   - If the cluster has a ClusterService service group configured, you can use the IP address configured in the service group or configure a new IP address for the Web console.
   - If you choose to configure a new IP address, type the IP address and associated subnet mask.
   - Select a network adapter for each node in the cluster. The wizard lists the public network adapters along with the adapters that were assigned a low priority.
2 Review the summary information and choose whether you want to bring the Web Console resources online when VCS is started and click **Configure**.

3 If you are finished with the configuration, click **Finish** to exit the wizard.

**Configuring notification**

Steps to configure notifier resource.

**To configure notification**

1 On the Notifier Options panel, specify the mode of notification to be configured and click **Next**.

You can configure VCS to generate SNMP (V2) traps on a designated server and/or send emails to designated recipients in response to certain events.
2. If you chose to configure SNMP, specify information about the SNMP console and click **Next**.

- Click a field in the SNMP Console column and type the name or IP address of the console. The specified SNMP console must be MIB 2.0 compliant.
- Click the corresponding field in the Severity column and select a severity level for the console.
- Click + to add a field; click - to remove a field.
- Enter an SNMP trap port. The default value is 162.
3 If you chose to configure SMTP, specify information about SMTP recipients and click **Next**.

- Type the name of the SMTP server.
- Click a field in the Recipients column and enter a recipient for notification. Enter recipients as admin@example.com.
- Click the corresponding field in the Severity column and select a severity level for the recipient. VCS sends messages of an equal or higher severity to the recipient.
- Click + to add fields; click - to remove a field.
4 On the Notifier Network Card Selection panel, specify the network information and click Next.

- If the cluster has a ClusterService service group configured, you can use the NIC resource configured in the service group or configure a new NIC resource for notification.
- If you choose to configure a new NIC resource, select a network adapter for each node in the cluster. Note that the wizard lists the public network adapters along with the adapters that were assigned a low priority.

5 Review the summary information and choose whether you want to bring the notification resources online when VCS is started and click Configure.

6 If you are done with the configuration, click Finish to exit the wizard.
Configuring the wide-area connector process for global clusters

Steps to configure wide-area connector resource for global clusters.

To configure the wide-area connector process for global clusters

1. On the GCO Network Selection panel, specify the network information and click **Next**.

   - If the cluster has a ClusterService service group configured, you can use the IP address configured in the service group or configure a new IP address.
   - If you choose to configure a new IP address, enter the IP address and associated subnet mask. Make sure that the specified IP address has a DNS entry.
   - Select a network adapter for each node in the cluster. The wizard lists the public network adapters along with the adapters that were assigned a low priority.

2. Review the summary information and choose whether you want to bring the resources online when VCS starts and click **Configure**.

3. Click **Finish** to exit the wizard.

The wizard does not set up a global cluster environment; it configures a resource for the wide-area connector, which is required for inter-cluster communication.

See “Setting up a global cluster” on page 580 for instructions on setting up a global cluster environment.
Deleting a cluster configuration

To delete a cluster configuration

1. Start the VCS Configuration wizard. Click **Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Cluster Configuration Wizard**.

2. Read the information on the Welcome panel and click **Next**.

3. In the Configuration Options panel, click **Cluster Operations** and click **Next**.

4. In the Domain Selection panel, select or type the name of the domain in which the cluster resides and click **Next**.

Do one of the following:

- To discover information about all the systems and users in the domain
  - Uncheck the **Specify systems and users manually** check box.
  - Click **Next**.
  
  Proceed to step 7 on page 456.

- To specify systems and user names manually (recommended for large domains)
  - Check the **Specify systems and users manually** check box.
    Additionally, you may instruct the wizard to retrieve a list of systems and users in the domain by selecting appropriate check boxes.
  - Click **Next**.
If you checked the **Retrieve system list from domain** check box, proceed to **step 6** on page 455. Otherwise proceed to the next step.

5 In the System Selection panel, type the name of the system and click **Add**.

Proceed to **step 7** on page 456.

6 In the System Selection panel, specify the nodes of the cluster to be deleted.

Enter the system name and click **Add** to add the system to the Selected Systems list. Alternatively, you can select the systems from the Domain Systems list and click the right-arrow icon.
If you specify only one node of an existing cluster, VCW discovers all nodes for that cluster.

7 In the Cluster Configuration Options panel, click Delete Cluster and then click Next.

8 In the Cluster Selection panel, select the cluster whose configuration is to be deleted and click Next.
   If you chose to specify the systems manually in step 4, only the clusters configured with the specified systems are displayed.

9 If you want to remove the VCS Helper Service user account from the administrative group of the all the nodes in the cluster, click Yes from the informational dialog box. Otherwise, click No.

10 In the Cluster User Information panel, enter the user name and password for a user with administrative privileges to the cluster and click OK.
   The Cluster User Information dialog box appears only when you delete a non-secure cluster.

11 Review the summary information and click Unconfigure.

12 The wizard starts running commands to remove the configuration from the cluster. After all commands have been successfully run, click Finish.
   VCW removes the cluster configuration; VCW does not unconfigure Symantec Product Authentication Service or uninstall SFW HA from the systems.
Predicting VCS behavior using VCS Simulator

- About VCS Simulator
- Administering VCS Simulator from the Java Console
- Administering VCS Simulator from the command line
About VCS Simulator

VCS Simulator enables you to simulate and test cluster configurations. Use VCS Simulator to view and modify service group and resource configurations and test failover behavior. VCS Simulator can be run on a stand-alone system and does not require any additional hardware.

VCS Simulator runs an identical version of the VCS High Availability Daemon (HAD) as in a cluster, ensuring that failover decisions are identical to those in an actual cluster.

You can test configurations from different operating systems using VCS Simulator. For example, you can run VCS Simulator on a Windows system and test VCS configurations for Windows, Linux, and Solaris clusters. VCS Simulator also enables creating and testing global clusters.

You can administer VCS Simulator from the Java Console or from the command line.

Simulator ports

VCS Simulator uses the following ports:

- Ports 15550 through 15559 and 15580 through 15585 to connect to the various cluster configurations.

- Ports 15560 through 15571 for the wide area connector (WAC) process. Set the WAC port to -1 to disable WAC simulation.
Administering VCS Simulator from the Java Console

The Simulator Console enables you to start, stop, and manage simulated clusters.

The console provides two views:

- Cluster View—Lists all simulated clusters.
- Global View—Lists global clusters.

Through the Java Console, VCS Simulator enables you to configure a simulated cluster panel, bring a system in an unknown state into an online state, simulate power loss for running systems, simulate resource faults, and save the configuration while VCS is offline. For global clusters, you can simulate the process of generating and clearing cluster faults.

You can run multiple simulated clusters on a system by using different port numbers for each cluster.

The Java Console provides the same views and features that are available for online configurations.

See "Administering the cluster from Cluster Manager (Java console)" on page 161.

Starting VCS Simulator from the Java Console

To start VCS Simulator from the Java Console (Windows)

◆ Click **Start > Programs > Symantec > Veritas VCS Simulator - Java Console**.
Creating a simulated cluster

You can start a sample cluster configuration or create a new simulated cluster.

To create a simulated cluster

1. In the Simulator console, click **Add Cluster**.
2. In the Add Cluster dialog box:

   - Enter a name for the new cluster.
   - Accept the suggested system name or enter a new name for a system in the cluster.
   - Enter a unique port number for the simulated cluster.
   - Select the platform for the cluster nodes.
   - If the cluster is part of a global cluster configuration, select the **Enable Global Cluster Option** check box and enter a unique port number for the wide-area connector (WAC) process.
   - Click **OK**.

VCS creates a simulated one-node cluster and creates a new directory for the cluster’s configuration files. VCS also creates a user called *admin* with Cluster Administrator privileges. You can start the simulated cluster and administer it by launching the Java Console.

Adding VCS type definitions

You must add the VCS type definitions using the Cluster Manager (Java Console) before attempting to load templates in Windows simulated clusters.
To add VCS type definitions

1. From the Start menu, click **Start > All Programs > Symantec > Veritas Cluster Server > Veritas Cluster Manager - Java Console** to start the Cluster Monitor.

2. Log on to the simulated cluster.

3. From the Cluster Explorer, click **File > Import Types**.

4. Click **Yes** on the dialog box that prompts you to switch the configuration to read/write mode.

5. In the Import Type dialog box, navigate to `%vcs_simulator_home%/conf/types/w2k` directory and select `LDMtypes.cf` and click **Import**.

The variable `%vcs_simulator_home%` is the path where the VCS Simulator is installed, typically `C:\Program Files\Veritas\VCS Simulator`.

6. Repeat step 5 and add `SFWTypes.cf`.

Deleting a cluster

Deleting a simulated cluster removes all files and directories that are associated with the cluster. Before deleting a cluster, make sure the cluster is not configured as a global cluster. You can delete global clusters from the Global View.

To delete a simulated cluster

1. From Simulator Explorer, select the cluster and click **Delete Cluster**.

2. In the confirmation dialog box, click **Yes**.

Starting a simulated cluster

Start the cluster to begin administering it.

To start a simulated cluster

1. In the Simulator console, select the cluster.

2. Click **Start Cluster**.

3. After the cluster starts, click **Launch Console** to administer the cluster.

4. Enter a valid user name and password to log on to the cluster.

VCS Simulator does not validate passwords; you can log on to a simulated cluster by entering a valid VCS user name. If you use the default
configuration, enter **admin** for the user name and any non-blank value for password. Cluster Explorer is launched upon initial logon, and the icons in the cluster panel change color to indicate an active panel.

**Verifying a simulated cluster configuration**

Verify that the configuration is valid.

**To verify the simulated cluster configuration**

1. In the Simulator console, select the cluster.
2. Click **Verify Configuration**.

**Simulating an existing cluster configuration**

Simulate an existing cluster configuration to test your cluster configuration.

**To simulate an existing cluster configuration**

1. In the Simulator console, click **Add Cluster**.
2. In the Add Cluster dialog box:
   - Enter a name for the new cluster.
   - Specify the system name. Make sure that you specify the name of one of the systems from the main.cf that you want to simulate.
   - Enter a unique port number for the simulated cluster.
   - Select the platform for the cluster nodes.
   - Click **OK**.

VCS creates a simulated one-node cluster and creates a new directory for the cluster's configuration files.

3. Open the directory `<SIMULATOR_DIR>\<CLUSTERNAME>\conf\config`.
4. Copy main.cf, types.cf, and all the required types files of the cluster that you want to simulate to this directory.
5. Click **Verify Configuration** on the Simulator console.
6. Click **Start Cluster**.

**Simulating a global cluster configuration**

Simulate a global cluster environment to test your global cluster configuration.

See “How VCS global clusters work” on page 572.
To simulate a global cluster configuration

1. Create the simulated clusters for the global configuration. 
   See "Creating a simulated cluster" on page 460. 
   Select the Enable Global Cluster Option check box and enter a unique port number for the wide-area connector (WAC) process.

2. In the Simulator console, click Make Global.

3. In the Make Global Configuration dialog box:
   - Select an existing global cluster or enter the name for a new global cluster.
   - From the Available Clusters list, select the clusters to add to the global cluster and click the right arrow. The clusters move to the Configured Clusters list.
   - Click OK.

Bringing a system up

Bring a system up to simulate a running system.

To bring a system up

1. From Cluster Explorer, click the Systems tab of the configuration tree.
2. Right-click the system in an unknown state, and click Up.
Powering off a system

1. From Cluster Explorer, click the **Systems** tab of the configuration tree.
2. Right-click the online system, and click **Power Off**.

Saving the offline configuration

1. From Cluster Explorer, click **Save Configuration As** from the **File** menu.
2. Enter the path location.
3. Click **OK**.

Simulating a resource fault

Use VCS Simulator to imitate a resource fault.

**To generate a resource fault**

1. From Cluster Explorer, click the **Service Groups** tab of the configuration tree.
2. Right-click an online resource, click **Fault Resource**, and click the system name.

Simulating cluster faults in global clusters

Use VCS Simulator to imitate the process of generating and clearing cluster faults.

See “**Monitoring alerts**” on page 255.

**To generate a cluster fault**

1. From Cluster Explorer, click the cluster in the configuration tree.
2. Right-click the cluster, click **Fault Cluster**, and click the cluster name.
   If any Cluster Explorer windows are open for the cluster being faulted, these become inoperative for a short period during which the Cluster Monitor tries to connect to the simulated High Availability Daemon for the cluster. Following this, an alert message appears and the Cluster Explorer windows close on their own.

**Note:** When a faulted cluster is brought up, its fault is automatically cleared. In case of a GCO configuration, the Remote Cluster status is also automatically updated. Hence there is no need to clear the cluster fault.
Simulating failed fire drills

Use VCS Simulator to demonstrate a failed fire drill. The following simulated clusters have fire drill service groups:

- SOL_ORA_SRDF_C2 (fire drill group is OracleGrp_fd)
- WIN_SQL_VVR_C2 (firedrill group is SQLPROD_fd)
- Win_Exch_2k3_Secondary (firedrill group is sample_fd)

See "Setting up a fire drill" on page 594.

To simulate a failed fire drill

1. Start Cluster Explorer and click the cluster in which you want to simulate the fire drill.
2. Select the fire drill service group from the Tree View, then select the Properties Tab in the right pane.
3. Click **Show all attributes**. Scroll down to choose the Tag attribute and double-click to edit the attribute value.
4. If prompted, switch the configuration to the read-write mode.
5. In the Edit Attribute window, set the value of the Tag attribute to the name of a critical resource in the FireDrill Service Group.
   - The Tag attribute values for service groups SQLPROD_fd (in cluster WIN_SQL_VVR_C2) and sample_fd (in cluster Win_Exch_2K3_secondary) should be blank before these modifications.
   - For the SQLPROD_fd fire-drill service group, set the attribute value to the name of the SQL Server instance - SQLServer2000-VSQL01_fd.
   - You do not need to change the attribute value for the Oracle group; by default, the Tag attribute of the OracleGrp_fd is set to the name of a critical resource.
6. Try to bring the FireDrill service group up. Right-click the service group in the Cluster Explorer and bring it online on a specified system. The FireDrill service group faults.

**Note:** To simulate a successful fire drill, keep the Tag attribute of the fire drill service group blank and bring the Firedrill service group online.
Predicting VCS behavior using VCS Simulator

Administering VCS Simulator from the command line

Start VCS Simulator before creating or administering simulated clusters.

**Note:** VCS Simulator treats clusters that are created from the command line and the Java Console separately. Hence, clusters that are created from the command line are not visible in the graphical interface. If you delete a cluster from the command line, you may see the cluster in the Java Console.

Starting VCS Simulator from the command line

**To start VCS Simulator from the command line (Windows)**

VCS Simulator installs platform-specific types.cf files at the path

\%VCS_SIMULATOR_HOME\%\types\.

The variable \%VCS_SIMULATOR_HOME\% represents the Simulator installation directory, typically C:\Program Files\Veritas\VCS Simulator\.

1. To simulate a cluster running a particular operating system, copy the types.cf file for the operating system from the types directory to

\%VCS_SIMULATOR_HOME\%\default_clus\conf\config\.

For example, if the cluster to be simulated runs on the AIX platform, copy the file types.cf.aix.

2. Add custom type definitions to the file, if required, and rename the file to types.cf.

3. Add VCS type definitions to the simulated cluster.

   See "Adding VCS type definitions" on page 460.

4. If you have a main.cf file to run in the simulated cluster, copy it to

   \%VCS_SIMULATOR_HOME\%\default_clus\conf\config\.

5. Start VCS Simulator:

   \%VCS_SIMULATOR_HOME\%\bin> hasim -start system_name

   The variable system_name represents a system name, as defined in the configuration file main.cf.

   This command starts Simulator on port 14153.

6. Add systems to the configuration, if desired:

   \%VCS_SIMULATOR_HOME\%\bin> hasim -sys -add system_name

7. Verify the state of each node in the cluster:

   \%VCS_SIMULATOR_HOME\%\bin> hasim -sys -state
Predicting VCS behavior using VCS Simulator

Administering VCS Simulator from the command line

See “To simulate global clusters from the command line” on page 467.

To simulate global clusters from the command line

1 Install VCS Simulator in a directory (sim_dir) on your system. See the section Installing VCS Simulator in the Veritas Cluster Server Installation Guide.

2 Set up the clusters on your system. Run the following command to add a cluster:

```
$ sim_dir/hasim -setupclus clusternam -simport
    port_no -wacport port_no
```

Do not use default_clus as the cluster name when simulating a global cluster.

VCS Simulator copies the sample configurations to the path sim_dir/ clusternam and creates a system named clusternam_sys1. For example, to add cluster clus_a using ports 15555 and 15575, run the following command:

```
$ sim_dir/hasim -setupclus clus_a -simport 15555 -wacport 15575
```

Similarly, add the second cluster:

```
$ sim_dir/hasim -setupclus clus_b -simport 15556 -wacport 15576
```

To create multiple clusters without simulating a global cluster environment, specify -1 for the wacport.

3 Start the simulated clusters:

```
$ sim_dir/hasim -start clusternam_sys1 -clus clusternam
```

4 Set the following environment variables to access VCS Simulator from the command line:

- VCS_SIM_PORT=port_number
- VCS_SIM_WAC_PORT=wacport

Note that you must set these variables for each simulated cluster, otherwise Simulator always connects default_clus, the default cluster.

You can use the Java Console to link the clusters and to configure global service groups.

See “Administering the cluster from Cluster Manager (Java console)” on page 161.

You can also edit the configuration file main.cf manually to create the global cluster configuration.
### Administering simulated clusters from the command line

The functionality of VCS Simulator commands mimic that of standard ha commands.

Predicting VCS behavior using VCS Simulator

Administering VCS Simulator from the command line
Administration-Beyond the basics

- Chapter 14, “VCS event notification” on page 535
- Chapter 15, “VCS event triggers” on page 551
Controlling VCS behavior

- About VCS behavior on resource faults
- Controlling VCS behavior at the service group level
- Controlling VCS behavior at the resource level
- Changing agent file paths and binaries
- Service group workload management
- Sample configurations depicting workload management
About VCS behavior on resource faults

VCS considers a resource faulted in the following situations:

- When the resource state changes unexpectedly. For example, an online resource going offline.
- When a required state change does not occur. For example, a resource failing to go online or offline when commanded to do so.

In many situations, VCS agents take predefined actions to correct the issue before reporting resource failure to the engine. For example, the agent may try to bring a resource online several times before declaring a fault.

When a resource faults, VCS takes automated actions to "clean up the faulted resource. The Clean function makes sure the resource is completely shut down before bringing it online on another node. This prevents concurrency violations.

When a resource faults, VCS takes all resources dependent on the faulted resource offline. The fault is thus propagated in the service group.

About critical and non-critical resources

The Critical attribute for a resource defines whether a service group fails over when the resource faults. If a resource is configured as non-critical (by setting the Critical attribute to 0) and no resources depending on the failed resource are critical, the service group will not fail over. VCS takes the failed resource offline and updates the group status to ONLINE|PARTIAL. The attribute also determines whether a service group tries to come online on another node if, during the group’s online process, a resource fails to come online.

VCS behavior diagrams

This section describes the default functionality of VCS when resources fault. The illustration displays the symbols used in this section.

<tr>
<td>Resource Coming Online</td>
<td>Faulted</td>
</tr>
</tbody>
</table>
**Scenario: Resource with critical parent faults**

The service group in the following example has five resources, of which resource R1 is configured as a critical resource.

When resource R2 faults, the fault is propagated up the dependency tree to resource R1. When the critical resource R1 goes offline, VCS must fault the service group and fail it over elsewhere in the cluster. VCS takes other resources in the service group offline in the order of their dependencies. After taking resources R3, R4, and R5 offline, VCS fails over the service group to another node.

**Scenario: Resource with non-critical parent faults**

The service group in the following example does not have any critical resources.

When resource R2 faults, the engine propagates the failure up the dependency tree. Neither resource R1 nor resource R2 are critical, so the fault does not result in the tree going offline or in service group failover.
Scenario: Resource with critical parent fails to come online

In the following example, when a command is issued to bring the service group online, resource R2 fails to come online.

VCS calls the Clean function for resource R2 and propagates the fault up the dependency tree. Resource R1 is set to critical, so the service group is taken offline and failed over to another node in the cluster.
Controlling VCS behavior at the service group level

This section describes how you can configure service group attributes to modify VCS behavior in response to resource faults.

About the AutoRestart attribute

If a persistent resource on a service group (GROUP_1) faults, VCS fails the service group over to another system if the following conditions are met:

- The AutoFailOver attribute is set.
- Another system in the cluster exists to which GROUP_1 can fail over.

If neither of these conditions is met, GROUP_1 remains offline and faulted, even after the faulted resource becomes online.

Setting the AutoRestart attribute enables a service group to be brought back online without manual intervention. If no failover targets are available, setting the AutoRestart attribute enables VCS to bring the group back online on the first available system after the group’s faulted resource came online on that system.

For example, NIC is a persistent resource. In some cases, when a system boots and VCS starts, VCS probes all resources on the system. When VCS probes the NIC resource, the resource may not be online because the networking is not up and fully operational. In such situations, VCS marks the NIC resource as faulted, and does not bring the service group online. However, when the NIC resource becomes online and if AutoRestart is enabled, the service group is brought online.

Controlling failover on service group or system faults

The AutoFailOver attribute configures service group behavior in response to service group and system faults.

0 VCS does not fail over the service group when a system or service group faults.

If a fault occurs in a service group, the group is taken offline, depending on whether any of its resources are configured as critical. If a system faults, the service group is not failed over to another system.
Controlling VCS behavior at the service group level

1. VCS automatically fails over the service group when a system or a service group faults, provided a suitable node exists for failover.

The service group attributes SystemZones and FailOverPolicy impact the failover behavior of the service group. For global clusters, the failover decision is also based on the ClusterFailOverPolicy. See “Service group attributes” on page 764.

Defining failover policies

The service group attribute FailOverPolicy governs how VCS calculates the target system for failover. There are three possible values for FailOverPolicy:

- **Priority**
  VCS selects the system with the lowest priority as the failover target. The Priority failover policy is ideal for simple two-node clusters or small clusters with few service groups.
  Priority is set in the SystemList attribute implicitly via ordering, such as SystemList = [SystemA, SystemB] or explicitly, such as SystemList = [SystemA=0, SystemB=1]. Priority is the default behavior.

- **RoundRobin**
  VCS selects the system running the fewest service groups as the failover target. This policy is ideal for large clusters running many service groups with similar server load characteristics (for example, similar databases or applications).

- **Load**
  The Load failover policy comprises the following components:
  System capacity and service group load, represented by the attributes Capacity and Load respectively.
  System limits and service group prerequisites, represented by the attributes Limits and Prerequisites, respectively.

About system zones

The SystemZones attribute enables you to create a subset of systems to use in an initial failover decision. This feature allows fine-tuning of application failover decisions, and yet retains the flexibility to fail over anywhere in the cluster.

If the attribute is configured, a service group tries to stay within its zone before choosing a host in another zone. For example, in a three-tier application infrastructure with Web, application, and database servers, you could create two system zones: one each for the application and the database. In the event of a failover, a service group in the application zone will try to fail over to another
node within the zone. If no nodes are available in the application zone, the group will fail over to the database zone, based on the configured load and limits.

In this configuration, excess capacity and limits on the database backend are kept in reserve to handle the larger load of a database failover. The application servers handle the load of service groups in the application zone. During a cascading failure, the excess capacity in the cluster is available to all service groups.

About load-based autostart

VCS provides a method to determine where a service group comes online when the cluster starts. Setting the AutoStartPolicy to Load instructs the VCS engine, HAD, to determine the best system on which to start the groups. VCS places service groups in an AutoStart queue for load-based startup as soon as the groups probe all running systems. VCS creates a subset of systems that meet all prerequisites and then chooses the system with the highest AvailableCapacity.

Set AutoStartPolicy = Load and configure the SystemZones attribute to establish a list of preferred systems on which to initially run a group.

Freezing service groups

Freezing a service group prevents VCS from taking any action when the service group or a system faults. Freezing a service group prevents dependent resources from going offline when a resource faults. It also prevents the Clean function from being called on a resource fault.

You can freeze a service group when performing operations on its resources from outside VCS control. This prevents VCS from taking actions on resources while your operations are on. For example, freeze a database group when using database controls to stop and start a database.
Controlling Clean behavior on resource faults

The ManageFaults attribute specifies whether VCS calls the Clean function when a resource in the service group faults. ManageFaults is a service group attribute; you can configure each service group to operate as desired.

- If the ManageFaults attribute is set to ALL, VCS calls the Clean function when a resource faults.
- If the ManageFaults attribute is set to NONE, VCS takes no action on a resource fault; it hangs the service group until administrative action can be taken. VCS marks the resource state as ADMIN_WAIT and does not fail over the service group until the resource fault is removed and the ADMIN_WAIT state is cleared.

VCS calls the resadminwait trigger when a resource enters the ADMIN_WAIT state due to a resource fault if the ManageFaults attribute is set to NONE. You can customize this trigger to provide notification about the fault. See “resadminwait event trigger” on page 561.

When ManageFaults is set to none and one of the following events occur, the resource enters the admin_wait state:

<table>
<thead>
<tr>
<th>Event</th>
<th>Resource state</th>
</tr>
</thead>
<tbody>
<tr>
<td>The offline function did not complete within the expected time.</td>
<td>ONLINE</td>
</tr>
<tr>
<td>The offline function was ineffective.</td>
<td>ONLINE</td>
</tr>
<tr>
<td>The online function did not complete within the expected time.</td>
<td>OFFLINE</td>
</tr>
<tr>
<td>The online function was ineffective.</td>
<td>OFFLINE</td>
</tr>
<tr>
<td>The resource was taken offline unexpectedly.</td>
<td>OFFLINE</td>
</tr>
<tr>
<td>For the online resource the monitor function consistently failed to complete within the expected time.</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>
Clearing resources in the ADMIN_WAIT state

When VCS sets a resource in the ADMIN_WAIT state, it invokes the resadminwait trigger according to the reason the resource entered the state.

See "resadminwait event trigger" on page 561.

To clear a resource

1. Take the necessary actions outside VCS to bring all resources into the required state.
2. Verify that resources are in the required state by issuing the command:
   ```bash
   hagrp -clearadminwait group -sys system
   ```
   This command clears the ADMIN_WAIT state for all resources. If VCS continues to detect resources that are not in the required state, it resets the resources to the ADMIN_WAIT state.
3. If resources continue in the ADMIN_WAIT state, repeat step 1 and step 2, or issue the following command to stop VCS from setting the resource to the ADMIN_WAIT state:
   ```bash
   hagrp -clearadminwait -fault group -sys system
   ```
   This command has the following results:
   - If the resadminwait trigger was called for reasons 0 or 1, the resource state is set as ONLINE|UNABLE_TO_OFFLINE.
   - If the resadminwait trigger was called for reasons 2, 3, or 4, the resource state is set as FAULTED. Please note that when resources are set as FAULTED for these reasons, the clean function is not called. Verify that resources in ADMIN_WAIT are in clean, OFFLINE state prior to invoking this command.

When a service group has a resource in the ADMIN_WAIT state, the following service group operations cannot be performed on the resource: online, offline, switch, and flush. Also, you cannot use the hastop command when resources are in the ADMIN_WAIT state. When this occurs, you must issue the hastop command with -force option only.
Controlling VCS behavior at the service group level

Controlling fault propagation

The FaultPropagation attribute defines whether a resource fault is propagated up the resource dependency tree. It also defines whether a resource fault causes a service group failover.

- If the FaultPropagation attribute is set to 1 (default), a resource fault is propagated up the dependency tree. If a resource in the path is critical, the service group is taken offline and failed over, provided the AutoFailOver attribute is set to 1.

- If the FaultPropagation is set to 0, resource faults are contained at the resource level. VCS does not take the dependency tree offline, thus preventing failover. If the resources in the service group remain online, the service group remains in the PARTIAL|FAULTED state. If all resources are offline or faulted, the service group remains in the OFFLINE| FAULTED state.

When a resource faults, VCS fires the resfault trigger and sends an SNMP trap. The trigger is called on the system where the resource faulted and includes the name of the faulted resource.

See “resfault event trigger” on page 562.
Customized behavior diagrams

The illustrations in this section depict how the ManageFaults and FaultPropagation attributes change VCS behavior when handling resource faults. The following illustration depicts the legends used in the section.

### Resource Color Code

- **Online**
- **Offline**
- **Faulted**
- **Online | Admin_Wait**
- **Offline | Admin_Wait**

### Scenario: Resource with a critical parent and ManageFaults=NONE

The service group in the following example has five resources. The ManageFaults attribute is set to NONE for resource R2.

If resource R2 fails, the resource is marked as ONLINE|ADMIN_WAIT. The Clean function is not called for the resource. VCS does not take any other resource offline.
Scenario: Resource with a critical parent and FaultPropagation=0

In the following example, the FaultPropagation attribute is set to 0.

When resource R2 faults, the Clean function is called and the resource is marked as faulted. The fault is not propagated up the tree, and the group is not taken offline.

VCS behavior for resources that support the intentional offline functionality

Certain agents can identify when an application has been intentionally shut down outside of VCS control.

For agents that support this functionality, if an administrator intentionally shuts down an application outside of VCS control, VCS does not treat it as a fault. VCS sets the service group state as offline or partial, depending on the state of other resources in the service group.

This feature allows administrators to stop applications without causing a failover. The feature is available for V51 agents.

About the IntentionalOffline attribute

To configure a resource to recognize an intentional offline of configured application, set the IntentionalOffline attribute to 1. Set the attribute to its default value of 0 to disable this functionality.

- If you set the attribute to 1: When the application is intentionally stopped outside of VCS control, the resource enters an OFFLINE state. This attribute does not affect VCS behavior on application failure. VCS continues to fault resources if managed corresponding applications fail.
If you set the attribute to 0: When the application is intentionally stopped outside of VCS control, the resource enters a FAULTED state.

**About the ExternalStateChanged attribute**

Use the ExternalStateChanged attribute to control service group behavior in response to a configured application is intentionally started or stopped outside of VCS control.

The attribute defines how VCS handles service group state when resources are intentionally brought online or taken offline outside of VCS control.

The attribute can take the following values:

- **OnlineGroup**: If the configured application is started outside of VCS control, VCS brings the corresponding service group online. If you attempt to start the application on a frozen node or service group, VCS brings the corresponding service group online once the node or service group is unfrozen.

- **OfflineGroup**: If the configured application is stopped outside of VCS control, VCS takes the corresponding service group offline.

- **OfflineHold**: If a configured application is stopped outside of VCS control, VCS sets the state of the corresponding VCS resource as offline. VCS does not take any parent resources or the service group offline.

*OfflineHold and OfflineGroup are mutually exclusive.*

**Controlling VCS behavior at the resource level**

This section describes how you can control VCS behavior at the resource level. Note that a resource is not considered faulted until the agent framework declares the fault to the VCS engine.

**About resource type attributes that control resource behavior**

The following attributes affect how the VCS agent framework reacts to problems with individual resources before informing the fault to the VCS engine.

**About the RestartLimit attribute**

The RestartLimit attribute defines whether VCS attempts to restart a failed resource before informing the engine of the fault.

If the RestartLimit attribute is set to a non-zero value, the agent attempts to restart the resource before declaring the resource as faulted. When restarting a failed resource, the agent framework calls the Clean function before calling the
Online function. However, setting the ManageFaults attribute to NONE prevents the Clean function from being called and prevents the Online function from being retried.

**About the OnlineRetryLimit attribute**
The OnlineRetryLimit attribute specifies the number of times the Online function is retried if the initial attempt to bring a resource online is unsuccessful.

When the OnlineRetryLimit set to a non-zero value, the agent framework calls the Clean function before rerunning the Online function. Setting the ManageFaults attribute to NONE prevents the Clean function from being called and also prevents the Online operation from being retried.

**About the ConfInterval attribute**
The ConfInterval attribute defines how long a resource must remain online without encountering problems before previous problem counters are cleared. The attribute controls when VCS clears the RestartCount, ToleranceCount and CurrentMonitorTimeoutCount values.

**About the ToleranceLimit attribute**
The ToleranceLimit attribute defines the number of times the Monitor routine should return an offline status before declaring a resource offline. This attribute is typically used when a resource is busy and appears to be offline. Setting the attribute to a non-zero value instructs VCS to allow multiple failing monitor cycles with the expectation that the resource will eventually respond. Setting a non-zero ToleranceLimit also extends the time required to respond to an actual fault.

**About the FaultOnMonitorTimeouts attribute**
The FaultOnMonitorTimeouts attribute defines whether VCS interprets a Monitor function timeout as a resource fault.

If the attribute is set to 0, VCS does not treat Monitor timeouts as a resource faults. If the attribute is set to 1, VCS interprets the timeout as a resource fault and the agent calls the Clean function to shut the resource down.

By default, the FaultOnMonitorTimeouts attribute is set to 4. This means that the Monitor function must time out four times in a row before the resource is marked faulted.
How VCS handles resource faults

This section describes the process VCS uses to determine the course of action when a resource faults.

VCS behavior when an online resource faults

In the following example, a resource in an online state is reported as being offline without being commanded by the agent to go offline.

- VCS first verifies the Monitor routine completes successfully in the required time. If it does, VCS examines the exit code returned by the Monitor routine. If the Monitor routine does not complete in the required time, VCS looks at the FaultOnMonitorTimeouts (FOMT) attribute.

- If FOMT=0, the resource will not fault when the Monitor routine times out. VCS considers the resource online and monitors the resource periodically, depending on the monitor interval.
  - If FOMT=1 or more, VCS compares the CurrentMonitorTimeoutCount (CMTC) with the FOMT value. If the monitor timeout count is not used up, CMTC is incremented and VCS monitors the resource in the next cycle.

- If FOMT= CMTC, this means that the available monitor timeout count is exhausted and VCS must now take corrective action.

- If the ManageFaults attribute is set to NONE, VCS marks the resource as ONLINE|ADMIN_WAIT and fires the resadminwait trigger. If the ManageFaults attribute is set to ALL, the resource enters a GOING_OFFLINE_WAIT state. VCS invokes the Clean function with the reason Monitor Hung.

- If the Clean function is successful (that is, Clean exit code = 0), VCS examines the value of the RestartLimit attribute. If Clean fails (exit code = 1), the resource remains online with the state UNABLE TO OFFLINE. VCS fires the resnotoff trigger and monitors the resource again.

- If the Monitor routine does not time out, it returns the status of the resource as being online or offline.

- If the ToleranceLimit (TL) attribute is set to a non-zero value, the Monitor cycle returns offline (exit code = 100) for a number of times specified by the ToleranceLimit and increments the ToleranceCount (TC). When the ToleranceCount equals the ToleranceLimit (TC = TL), the agent declares the resource as faulted.

- If the Monitor routine returns online (exit code = 110) during a monitor cycle, the agent takes no further action. The ToleranceCount attribute is reset to 0 when the resource is online for a period of time specified by the ConfInterval attribute.
If the resource is detected as being offline a number of times specified by the ToleranceLimit before the ToleranceCount is reset (TC = TL), the resource is considered failed.

- After the agent determines the resource is not online, VCS checks the Frozen attribute for the service group. If the service group is frozen, VCS declares the resource faulted and calls the resfault trigger. No further action is taken.

- If the service group is not frozen, VCS checks the ManageFaults attribute. If ManageFaults=NONE, VCS marks the resource state as ONLINE|ADMIN_WAIT and calls the resadminwait trigger. If ManageFaults=ALL, VCS calls the Clean function with the CleanReason set to Unexpected Offline.

- If the Clean function fails (exit code = 1) the resource remains online with the state UNABLE TO OFFLINE. VCS fires the resnotoff trigger and monitors the resource again. The resource enters a cycle of alternating Monitor and Clean functions until the Clean function succeeds or a user intervenes.

- If the Clean function is successful, VCS examines the value of the RestartLimit (RL) attribute. If the attribute is set to a non-zero value, VCS increments the RestartCount (RC) attribute and invokes the Online function. This continues till the value of the RestartLimit equals that of the RestartCount. At this point, VCS attempts to monitor the resource.

VCS behavior when a resource fails to come online

In the following example, the agent framework invokes the Online function for an offline resource. The resource state changes to WAITING TO ONLINE.

- If the Online function times out, VCS examines the value of the ManageFaults attribute.

- If ManageFaults is set to NONE, the resource state changes to OFFLINE|ADMIN_WAIT.

  If ManageFaults is set to ALL, VCS calls the Clean function with the CleanReason set to Online Hung.

- If the Online function does not time out, VCS invokes the Monitor function. The Monitor routine returns an exit code of 110 if the resource is online. Otherwise, the Monitor routine returns an exit code of 100.

- VCS examines the value of the OnlineWaitLimit (OWL) attribute. This attribute defines how many monitor cycles can return an offline status
before the agent framework declares the resource faulted. Each successive
Monitor cycle increments the OnlineWaitCount (OWC) attribute. When
OWL= OWC (or if OWL= 0), VCS determines the resource has faulted.

- VCS then examines the value of the ManageFaults attribute. If the
  ManageFaults is set to NONE, the resource state changes to
  OFFLINE\ADMIN\WAIT.
  If the ManageFaults is set to ALL, VCS calls the Clean function with the
  CleanReason set to Online Ineffective.

- If the Clean function is not successful (exit code = 1), the agent monitors the
  resource. It determines the resource is offline, and calls the Clean function
  with the Clean Reason set to Online Ineffective. This cycle continues till the
  Clean function is successful, after which VCS resets the OnlineWaitCount
  value.

- If the OnlineRetryLimit (ORL) is set to a non-zero value, VCS increments the
  OnlineRetryCount (ORC) and invokes the Online function. This starts the
cycle all over again. If ORL = ORC, or if ORL = 0, VCS assumes that the Online operation has failed and declares the resource as faulted.
Controlling VCS behavior at the resource level

- **A**: Resource Offline
  - Online. Resource Waiting to Online
    - Online Timeout?
      - NO
      - Resource Online
        - Monitor Exit Code
          - ORL > NONE
          - ORC = ORC+1

                    - YES
                    - B
                    - NO
                  - NO
VCS behavior after a resource is declared faulted

After a resource is declared faulted, VCS fires the resfault trigger and examines the value of the FaultPropagation attribute.

- If FaultPropagation is set to 0, VCS does not take other resources offline, and changes the group state to OFFLINE|FAULTED or PARTIAL|FAULTED. The service group does not fail over.
  - If FaultPropagation is set to 1, VCS takes all resources in the dependent path of the faulted resource offline, up to the top of the tree.

- VCS then examines if any resource in the dependent path is critical. If no resources are critical, the service group is left in its OFFLINE|FAULTED or PARTIAL|FAULTED state. If a resource in the path is critical, VCS takes the all resources in the service group offline in preparation of a failover.

- If the AutoFailOver attribute is set to 0, the service group is not failed over; it remains in a faulted state. If AutoFailOver is set to 1, VCS examines if any systems in the service group's SystemList are possible candidates for failover. If no suitable systems exist, the group remains faulted and VCS calls the nofailover trigger. If eligible systems are available, VCS examines the FailOverPolicy to determine the most suitable system to which to fail over the service group.
- If FailOverPolicy is set to Load, a NoFailover situation may occur because of restrictions placed on service groups and systems by Service Group Workload Management.
Controlling VCS behavior at the resource level

NO

Service group offline in Faulted state. nofailover trigger.

FAILover based on FailOverPolicy
Disabling resources

Disabling a resource means that the resource is no longer monitored by a VCS agent, and that the resource cannot be brought online or taken offline. The agent starts monitoring the resource after the resource is enabled. The resource attribute Enabled determines whether a resource is enabled or disabled. A persistent resource can be disabled when all its parents are offline. A non-persistent resource can be disabled when the resource is in an OFFLINE state.

When to disable a resource

Typically, resources are disabled when one or more resources in the service group encounter problems and disabling the resource is required to keep the service group online or to bring it online.

Note: Disabling a resource is not an option when the entire service group requires disabling. In that case, set the service group attribute Enabled to 0.

To disable a resource

To disable the resource when VCS is running:

```
hares -modify resource_name Enabled 0
```

To have the resource disabled initially when VCS is started, set the resource’s Enabled attribute to 0 in main.cf.

Limitations of disabling resources

When VCS is running, there are certain prerequisites to be met before the resource is disabled successfully.

- An online non-persistent resource cannot be disabled. It must be in a clean OFFLINE state. (The state must be OFFLINE and IState must be NOT WAITING.)

- If it is a persistent resource and the state is ONLINE on some of the systems, all dependent resources (parents) must be in clean OFFLINE state. (The state must be OFFLINE and IState must be NOT WAITING)

Therefore, before disabling the resource you may be required to take it offline (if it is non-persistent) and take other resources offline in the service group.
**Additional considerations for disabling resources**

- When a group containing disabled resources is brought online, the online transaction is not propagated to the disabled resources. Children of the disabled resource are brought online by VCS only if they are required by another enabled resource.

- You can bring children of disabled resources online if necessary.

- When a group containing disabled resources is taken offline, the offline transaction is propagated to the disabled resources.

The following figures show how a service group containing disabled resources is brought online.

![Diagram showing resource relationships and statuses](image)

In the figure above, Resource_3 is disabled. When the service group is brought online, the only resources brought online by VCS are Resource_1 and Resource_2 (Resource_2 is brought online first) because VCS recognizes Resource_3 is disabled. In accordance with online logic, the transaction is not propagated to the disabled resource.
In the figure below, Resource_2 is disabled. When the service group is brought online, resources 1, 3, 4 are also brought online (Resource_4 is brought online first). Note Resource_3, the child of the disabled resource, is brought online because Resource_1 is enabled and is dependent on it.

**How disabled resources affect group states**

When a service group is brought online containing non-persistent, disabled resources whose AutoStart attributes are set to 1, the group state is PARTIAL, even though enabled resources with Autostart=1 are online. This is because the disabled resource is considered for the group state.

To have the group in the ONLINE state when enabled resources with AutoStart set to 1 are in ONLINE state, set the AutoStart attribute to 0 for the disabled, non-persistent resources.
Changing agent file paths and binaries

VCS runs agent binaries from the path `%VCS_HOME%\bin\agent_name\`. You can instruct VCS to run a different set of agent binaries or scripts by specifying values for the AgentFile and AgentDirectory attributes.

- **AgentFile**— Specify a value for this attribute if the name of the agent binary is not the same as that of the resource type. For example, if the resource type is NetBackup and the agent binary is called NBU.dll, set the AgentFile attribute to NBU.dll.

- **AgentDirectory**— Specify a value for this attribute if the agent is not installed at the default location. When you specify the agent directory, VCS looks for the agent file (AgentNameAgent) in the agent directory. If the agent file name does not conform to the AgentNameAgent convention, configure the AgentFile attribute.

  For example, if the NetBackup agent is installed at `C:\Program Files\VERITAS\NetBackup`, specify this path as the attribute value.

To change the path of an agent

- Before configuring a resource for the agent, add AgentFile and AgentDirectory as static attributes to the agent’s resource type.

  ```
  haattr -add -static resource_type AgentFile "binary_name.dll"
  haattr -add -static resource_type AgentDirectory "C:\Program Files\agent_path"
  ```
Service group workload management

Workload management is a load-balancing mechanism that determines which system hosts an application during startup, or after an application or server fault.

Service Group Workload Management provides tools for making intelligent decisions about startup and failover locations, based on system capacity and resource availability.

Enabling service group workload management

The service group attribute FailOverPolicy governs how VCS calculates the target system for failover. Set FailOverPolicy to Load to enable service group workload management.

See "Controlling VCS behavior at the resource level" on page 485

About system capacity and service group load

The Load and Capacity construct allows the administrator to define a fixed amount of resources a server provides (Capacity), and a fixed amount of resources a specific service group is expected to utilize (Load).

The system attribute Capacity sets a fixed load-handling capacity for servers. Define this attribute based on system requirements.

The service group attribute Load sets a fixed demand for service groups. Define this attribute based on application requirements.

When a service group is brought online, its load is subtracted from the system’s capacity to determine available capacity. VCS maintains this info in the attribute AvailableCapacity.

When a failover occurs, VCS determines which system has the highest available capacity and starts the service group on that system. During a failover involving multiple service groups, VCS makes failover decisions serially to facilitate a proper load-based choice.

System capacity is a soft restriction; in some situations, value of the Capacity attribute could be less than zero. During some operations, including cascading failures, the value of the AvailableCapacity attribute could be negative.

Static load versus dynamic load

Dynamic load is an integral component of the Service Group Workload Management framework. Typically, HAD sets remaining capacity with the function:
AvailableCapacity = Capacity - (sum of Load values of all online service groups)

If the DynamicLoad attribute is defined, its value overrides the calculated Load values with the function:

AvailableCapacity = Capacity - DynamicLoad

This enables better control of system loading values than estimated service group loading (static load). However, this requires setting up and maintaining a load estimation package outside VCS. It also requires modifying the configuration file main.cf manually.

Note that the DynamicLoad (specified with hasys -load) is subtracted from the Capacity as an integer and not a percentage value. For example, if a system's capacity is 200 and the load estimation package determines the server is 80 percent loaded, it must inform VCS that the DynamicLoad value is 160 (not 80).

About overload warning

Overload warning provides the notification component of the Load policy. When a server sustains the preset load level (set by the attribute LoadWarningLevel) for a preset time (set by the attribute LoadTimeThreshold), VCS invokes the loadwarning trigger.

See “Using event triggers” on page 552
See “System attributes” on page 779.

The loadwarning trigger is a user-defined script or application designed to carry out specific actions. It is invoked once, when system load exceeds the LoadWarningLevel for the LoadTimeThreshold. It is not invoked again until the LoadTimeCounter, which determines how many seconds system load has been above LoadWarningLevel, is reset.

About system limits and service group prerequisites

Limits is a system attribute and designates which resources are available on a system, including shared memory segments and semaphores.

Prerequisites is a service group attribute and helps manage application requirements. For example, a database may require three shared memory segments and 10 semaphores. VCS Load policy determines which systems meet the application criteria and then selects the least-loaded system.

If the prerequisites defined for a service group are not met on a system, the service group cannot be brought online on the system.

When configuring these attributes, define the service group’s prerequisites first, then the corresponding system limits. Each system can have a different limit.
and there is no cap on the number of group prerequisites and system limits. Service group prerequisites and system limits can appear in any order.

You can also use these attributes to configure the cluster as N-to-1 or N-to-N. For example, to ensure that only one service group can be online on a system at a time, add the following entries to the definition of each group and system:

```plaintext
Prerequisites = { GroupWeight = 1 }
Limits = { GroupWeight = 1 }
```

System limits and group prerequisites work independently of FailOverPolicy. Prerequisites determine the eligible systems on which a service group can be started. When a list of systems is created, HAD then follows the configured FailOverPolicy.

**Using capacity and limits**

When selecting a node as a failover target, VCS selects the system that meets the service group’s prerequisites and has the highest available capacity. If multiple systems meet the prerequisites and have the same available capacity, VCS selects the system appearing lexically first in the SystemList.

Systems having an available capacity of less than the percentage set by the LoadWarningLevel attribute, and those remaining at that load for longer than the time specified by the LoadTimeThreshold attribute invoke the loadwarning trigger.
Sample configurations depicting workload management

This section lists some sample configurations that use the concepts described in this chapter.

System and Service group definitions

The main.cf in this example shows various Service Group Workload Management attributes in a system definition and a service group definition. See “VCS attributes” on page 745.

```
include "types.cf"
cluster SGWM-demo {
    
    system LargeServer1 {
        Capacity = 200
        Limits = ( ShrMemSeg=20, Semaphores=10, Processors=12 )
        LoadWarningLevel = 90
        LoadTimeThreshold = 600
    }

    group G1 {
        SystemList = { LargeServer1, LargeServer2, MedServer1, MedServer2 }
        SystemZones = { LargeServer1=0, LargeServer2=0, MedServer1=1, MedServer2=1 }
        AutoStartPolicy = Load
        AutoStartList = { MedServer1, MedServer2 }
        FailOverPolicy = Load
        Load = 100
        Prerequisites = { ShrMemSeg=10, Semaphores=5, Processors=6 }
    }
```
Sample configuration: Basic four-node cluster

```plaintext
include "types.cf"
cluster SGWM-demo

system Server1 (  
    Capacity = 100  
)

system Server2 (  
    Capacity = 100  
)

system Server3 (  
    Capacity = 100  
)

system Server4 (  
    Capacity = 100  
)

group G1 (  
    SystemList = { Server1, Server2, Server3, Server4 }  
    AutoStartPolicy = Load  
    AutoStartList = { Server1, Server2, Server3, Server4 }  
    FailOverPolicy = Load  
    Load = 20  
)

group G2 (  
    SystemList = { Server1, Server2, Server3, Server4 }  
    AutoStartPolicy = Load  
    AutoStartList = { Server1, Server2, Server3, Server4 }  
    FailOverPolicy = Load  
    Load = 40  
)

group G3 (  
    SystemList = { Server1, Server2, Server3, Server4 }  
    AutoStartPolicy = Load  
    AutoStartList = { Server1, Server2, Server3, Server4 }  
    FailOverPolicy = Load  
    Load = 30  
)
```
Sample configurations depicting workload management

```plaintext

group G4 {
    SystemList = { Server1, Server2, Server3, Server4 }
    AutoStartPolicy = Load
    AutoStartList = { Server1, Server2, Server3, Server4 }
    FailOverPolicy = Load
    Load = 10
}

group G5 {
    SystemList = { Server1, Server2, Server3, Server4 }
    AutoStartPolicy = Load
    AutoStartList = { Server1, Server2, Server3, Server4 }
    FailOverPolicy = Load
    Load = 50
}

group G6 {
    SystemList = { Server1, Server2, Server3, Server4 }
    AutoStartPolicy = Load
    AutoStartList = { Server1, Server2, Server3, Server4 }
    FailOverPolicy = Load
    Load = 30
}

group G7 {
    SystemList = { Server1, Server2, Server3, Server4 }
    AutoStartPolicy = Load
    AutoStartList = { Server1, Server2, Server3, Server4 }
    FailOverPolicy = Load
    Load = 20
}

group G8 {
    SystemList = { Server1, Server2, Server3, Server4 }
    AutoStartPolicy = Load
    AutoStartList = { Server1, Server2, Server3, Server4 }
    FailOverPolicy = Load
    Load = 40
}
```
AutoStart operation

In this configuration, assume that groups probe in the same order they are described, G1 through G8. Group G1 chooses the system with the highest AvailableCapacity value. All systems have the same available capacity, so G1 starts on Server1 because this server is lexically first. Groups G2 through G4 follow on Server2 through Server4. With the startup decisions made for the initial four groups, the cluster configuration resembles:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server1</td>
<td>80</td>
<td>G1</td>
</tr>
<tr>
<td>Server2</td>
<td>60</td>
<td>G2</td>
</tr>
<tr>
<td>Server3</td>
<td>70</td>
<td>G3</td>
</tr>
<tr>
<td>Server4</td>
<td>90</td>
<td>G4</td>
</tr>
</tbody>
</table>

As the next groups come online, group G5 starts on Server4 because this server has the highest AvailableCapacity value. Group G6 then starts on Server1 with AvailableCapacity of 80. Group G7 comes online on Server3 with AvailableCapacity of 70 and G8 comes online on Server2 with AvailableCapacity of 60.

The cluster configuration now resembles:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server1</td>
<td>50</td>
<td>G1 and G6</td>
</tr>
<tr>
<td>Server2</td>
<td>20</td>
<td>G2 and G8</td>
</tr>
<tr>
<td>Server3</td>
<td>50</td>
<td>G3 and G7</td>
</tr>
<tr>
<td>Server4</td>
<td>40</td>
<td>G4 and G5</td>
</tr>
</tbody>
</table>

In this configuration, Server2 fires the loadwarning trigger after 600 seconds because it is at the default LoadWarningLevel of 80 percent.
Failure scenario
In the first failure scenario, Server4 fails. Group G4 chooses Server1 because Server1 and Server3 have AvailableCapacity of 50 and Server1 is lexically first. Group G5 then comes online on Server3. Serializing the failover choice allows complete load-based control and adds less than one second to the total failover time.

Following the first failure, the configuration now resembles:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server1</td>
<td>40</td>
<td>G1, G6, and G4</td>
</tr>
<tr>
<td>Server2</td>
<td>20</td>
<td>G2 and G8</td>
</tr>
<tr>
<td>Server3</td>
<td>0</td>
<td>G3, G7, and G5</td>
</tr>
</tbody>
</table>

In this configuration, Server3 fires the loadwarning trigger to notify that the server is overloaded. An administrator can then switch group G7 to Server1 to balance the load across groups G1 and G3. When Server4 is repaired, it rejoins the cluster with an AvailableCapacity value of 100, making it the most eligible target for a failover group.

Cascading failure scenario
If Server3 fails before Server4 can be repaired, group G3 chooses Server1, group G5 chooses Server2, and group G7 chooses Server1. This results in the following configuration:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server1</td>
<td>-10</td>
<td>G1, G6, G4, G3, and G7</td>
</tr>
<tr>
<td>Server2</td>
<td>-30</td>
<td>G2, G8, and G5</td>
</tr>
</tbody>
</table>

Server1 fires the loadwarning trigger to notify that it is overloaded.
Sample configuration: Complex four-node cluster

The cluster in this example has two large enterprise servers (LargeServer1 and LargeServer2) and two medium-sized servers (MedServer1 and MedServer2). It has four service groups, G1 through G4, with various loads and prerequisites. Groups G1 and G2 are database applications with specific shared memory and semaphore requirements. Groups G3 and G4 are middle-tier applications with no specific memory or semaphore requirements.

```bash
#include "types.cf"
cluster SGWM-demo (

  system LargeServer1 (  
    Capacity = 200  
    Limits = { ShrMemSeg=20, Semaphores=10, Processors=12 }  
    LoadWarningLevel = 90  
    LoadTimeThreshold = 600  
  )

  system LargeServer2 (  
    Capacity = 200  
    Limits = { ShrMemSeg=20, Semaphores=10, Processors=12 }  
    LoadWarningLevel = 70  
    LoadTimeThreshold = 300  
  )

  system MedServer1 (  
    Capacity = 100  
    Limits = { ShrMemSeg=10, Semaphores=5, Processors=6 }  
  )

  system MedServer2 (  
    Capacity = 100  
    Limits = { ShrMemSeg=10, Semaphores=5, Processors=6 }  
  )

)```
Sample configurations depicting workload management

group G1
SystemList = { LargeServer1, LargeServer2, MedServer1, MedServer2 }
SystemZones = { LargeServer1=0, LargeServer2=0, MedServer1=1, MedServer2=1 }
AutoStartPolicy = Load
AutoStartList = { LargeServer1, LargeServer2 }
FailOverPolicy = Load
Load = 100
Prerequisites = { ShrMemSeg=10, Semaphores=5, Processors=6 }

group G2
SystemList = { LargeServer1, LargeServer2, MedServer1, MedServer2 }
SystemZones = { LargeServer1=0, LargeServer2=0, MedServer1=1, MedServer2=1 }
AutoStartPolicy = Load
AutoStartList = { LargeServer1, LargeServer2 }
FailOverPolicy = Load
Load = 100
Prerequisites = { ShrMemSeg=10, Semaphores=5, Processors=6 }

group G3
SystemList = { LargeServer1, LargeServer2, MedServer1, MedServer2 }
SystemZones = { LargeServer1=0, LargeServer2=0, MedServer1=1, MedServer2=1 }
AutoStartPolicy = Load
AutoStartList = { MedServer1, MedServer2 }
FailOverPolicy = Load
Load = 30

group G4
SystemList = { LargeServer1, LargeServer2, MedServer1, MedServer2 }
SystemZones = { LargeServer1=0, LargeServer2=0, MedServer1=1, MedServer2=1 }
AutoStartPolicy = Load
AutoStartList = { MedServer1, MedServer2 }
FailOverPolicy = Load
Load = 20
### AutoStart operation

In this configuration, the AutoStart sequence resembles:

- G1—LargeServer1
- G2—LargeServer2
- G3—MedServer1
- G4—MedServer2

All groups begin a probe sequence when the cluster starts. Groups G1 and G2 have an AutoStartList of LargeServer1 and LargeServer2. When these groups probe, they are queued to go online on one of these servers, based on highest AvailableCapacity value. If G1 probes first, it chooses LargeServer1 because LargeServer1 and LargeServer2 both have an AvailableCapacity of 200, but LargeServer1 is lexically first. Groups G3 and G4 use the same algorithm to determine their servers.

### Normal operation

The configuration resembles:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>CurrentLimits</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>LargeServer1</td>
<td>100</td>
<td>ShrMemSeg=10, Semaphores=5, Processors=6</td>
<td>G1</td>
</tr>
<tr>
<td>LargeServer2</td>
<td>100</td>
<td>ShrMemSeg=10, Semaphores=5, Processors=6</td>
<td>G2</td>
</tr>
<tr>
<td>MedServer1</td>
<td>70</td>
<td>ShrMemSeg=10, Semaphores=5, Processors=6</td>
<td>G3</td>
</tr>
<tr>
<td>MedServer2</td>
<td>80</td>
<td>ShrMemSeg=10, Semaphores=5, Processors=6</td>
<td>G4</td>
</tr>
</tbody>
</table>

### Failure scenario

In this scenario, if LargeServer2 fails, VCS scans all available systems in group G2's SystemList that are in the same SystemZone and creates a subset of systems that meet the group's prerequisites. In this case, LargeServer1 meets all...
required Limits. Group G2 is brought online on LargeServer1. This results in the following configuration:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>CurrentLimits</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>LargeServer1</td>
<td>0</td>
<td>ShrMemSeg=0</td>
<td>G1, G2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=0</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Processors=0</td>
<td></td>
</tr>
<tr>
<td>MedServer1</td>
<td>70</td>
<td>ShrMemSeg=10</td>
<td>G3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Processors=6</td>
<td></td>
</tr>
<tr>
<td>MedServer2</td>
<td>80</td>
<td>ShrMemSeg=10</td>
<td>G4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Processors=6</td>
<td></td>
</tr>
</tbody>
</table>

After 10 minutes (LoadTimeThreshold = 600) VCS fires the loadwarning trigger on LargeServer1 because the LoadWarningLevel exceeds 90 percent.

**Cascading failure scenario**

In this scenario, another system failure can be tolerated because each system has sufficient Limits to accommodate the service group running on its peer. If MedServer1 fails, its groups can fail over to MedServer2.

If LargeServer1 fails, the failover of the two groups running on it is serialized. The first group lexically, G1, chooses MedServer2 because the server meets the required Limits and has AvailableCapacity value. Group G2 chooses MedServer1 because it is the only remaining system that meets the required Limits.
Sample configuration: Server consolidation

The following configuration has a complex eight-node cluster running multiple applications and large databases. The database servers, LargeServer1, LargeServer2, and LargeServer3, are enterprise systems. The middle-tier servers running multiple applications are MedServer1, MedServer2, MedServer3, MedServer4, and MedServer5.

In this configuration, the database zone (system zone 0) can handle a maximum of two failures. Each server has Limits to support a maximum of three database service groups. The application zone has excess capacity built into each server.

The servers running the application groups specify Limits to support one database, even though the application groups do not run prerequisites. This allows a database to fail over across system zones and run on the least-loaded server in the application zone.

```
include "types.cf"
cluster SGWM-demo {

    system LargeServer1 {
        Capacity = 200
        Limits = { ShrMemSeg=15, Semaphores=30, Processors=18 }
        LoadWarningLevel = 80
        LoadTimeThreshold = 900
    }

    system LargeServer2 {
        Capacity = 200
        Limits = { ShrMemSeg=15, Semaphores=30, Processors=18 }
        LoadWarningLevel=80
        LoadTimeThreshold=900
    }

    system LargeServer3 {
        Capacity = 200
        Limits = { ShrMemSeg=15, Semaphores=30, Processors=18 }
        LoadWarningLevel=80
        LoadTimeThreshold=900
    }

    system MedServer1 {
        Capacity = 100
        Limits = { ShrMemSeg=5, Semaphores=10, Processors=6 }
    }
```
Controlling VCS behavior
Sample configurations depicting workload management

```
system MedServer2 {
    Capacity = 100
    Limits = { ShrMemSeg=5, Semaphores=10, Processors=6 }
}

system MedServer3 {
    Capacity = 100
    Limits = { ShrMemSeg=5, Semaphores=10, Processors=6 }
}

system MedServer4 {
    Capacity = 100
    Limits = { ShrMemSeg=5, Semaphores=10, Processors=6 }
}

system MedServer5 {
    Capacity = 100
    Limits = { ShrMemSeg=5, Semaphores=10, Processors=6 }
}

group Database1 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }

}
```
Controlling VCS behavior

Sample configurations depicting workload management

```plaintext
group Database3 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    AutoStartList = { LargeServer1, LargeServer2, LargeServer3 }
    FailOverPolicy = Load
    Load = 100
    Prerequisites = { ShrMemSeg=5, Semaphores=10, Processors=6 }
}

group Application1 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    FailOverPolicy = Load
    Load = 50
}

group Application2 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    FailOverPolicy = Load
    Load = 50
}
```

```
group Application3 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    FailOverPolicy = Load
    Load = 50
}

group Application4 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    FailOverPolicy = Load
    Load = 50
}

group Application5 {
    SystemList = { LargeServer1, LargeServer2, LargeServer3, MedServer1, MedServer2, MedServer3, MedServer4, MedServer5 }
    SystemZones = { LargeServer1=0, LargeServer2=0, LargeServer3=0, MedServer1=1, MedServer2=1, MedServer3=1, MedServer4=1, MedServer5=1 }
    AutoStartPolicy = Load
    FailOverPolicy = Load
    Load = 50
}
AutoStart operation

Based on the preceding main.cf example, the AutoStart sequence resembles:

```
Database1  LargeServer1
Database2  LargeServer2
Database3  LargeServer3
Application1  MedServer1
Application2  MedServer2
Application3  MedServer3
Application4  MedServer4
Application5  MedServer5
```

Normal operation

The configuration resembles:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>CurrentLimits</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>LargeServer1</td>
<td>100</td>
<td>ShrMemSeg=10</td>
<td>Database1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=20</td>
<td></td>

</table>
Sample configurations depicting workload management

**Failure scenario**

In the following example, LargeServer3 fails. VCS scans all available systems in the SystemList for the Database3 group for systems in the same SystemZone and identifies systems that meet the group's prerequisites. In this case, LargeServer1 and LargeServer2 meet the required Limits. Database3 is brought online on LargeServer1. This results in the following configuration:

<table>
<thead>
<tr>
<th>Server</th>
<th>AvailableCapacity</th>
<th>CurrentLimits</th>
<th>Online Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>MedServer4</td>
<td>50</td>
<td>ShrMemSeg=5</td>
<td>Application4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=10</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Processors=6</td>
<td></td>
</tr>
<tr>
<td>MedServer5</td>
<td>50</td>
<td>ShrMemSeg=5</td>
<td>Application5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Semaphores=10</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Processors=6</td>
<td></td>
</tr>
</tbody>
</table>

In this scenario, further failure of either system can be tolerated because each has sufficient Limits available to accommodate the additional service group.

**Cascading failure scenario**

If the performance of a database is unacceptable with two database groups running on a single server, the SystemZones policy can help expedite performance. Failing over a database group into the application zone has the effect of resetting the group's preferred zone. For example, in the above scenario Database3 was moved to LargeServer1. The administrator could reconfigure the application zone to move two application groups to a single system. The database application can then be switched to the empty application server (MedServer1–MedServer5), which would put Database3 in Zone1 (application zone). If a failure occurs in Database3, the group selects the least-loaded server in the application zone for failover.
The role of service group dependencies

- About service group dependencies
- Service group dependency configurations
- Group Dependency FAQs
- Linking service groups
- VCS behavior with service group dependencies
About service group dependencies

Service groups can be dependent on each other. The dependent group is the *parent* and the other group is the *child*. For example a finance application (parent) may require that the database application (child) is online before it comes online. While service group dependencies offer more features to manage application service groups, they create more complex failover configurations.

A service group may function both as a parent and a child. Veritas Cluster Server supports five levels of service group dependencies.
Dependency links

The dependency relationship between a parent and a child is called a link. The link is characterized by the dependency category, the location of the service groups, and the rigidity of dependency.

- A dependency may be online, or offline.
- A dependency may be local, global, or remote.
- A dependency may be soft, firm, or hard with respect to the rigidity of the constraints between parent and child service group.

You can customize the behavior of service groups by choosing the right combination of the dependency category, location, and rigidity.

Dependency categories: online or offline dependencies

Dependency categories determine the relationship of the parent group with the state of the child group.

<table>
<thead>
<tr>
<th>Dependency Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Online group dependency</td>
<td>The parent group must wait for the child group to be brought online before it can start. For example, to configure a database application and a database service as two separate groups, specify the database application as the parent, and the database service as the child.</td>
</tr>
<tr>
<td>Offline group dependency</td>
<td>The parent group can be started only if the child group is offline and vice versa. This behavior prevents conflicting applications from running on the same system. For example, configure a test application on one system as the parent and the production application on another system as the child.</td>
</tr>
</tbody>
</table>

Dependency location: local, global, or remote dependencies

The relative location of the parent and child service groups determines whether the dependency between them is a local, global, or remote.

<table>
<thead>
<tr>
<th>Dependency Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local dependency</td>
<td>The parent group depends on the child group being online or offline on the same system.</td>
</tr>
<tr>
<td>Global dependency</td>
<td>An instance of the parent group depends on one or more instances of the child group being online on any system.</td>
</tr>
<tr>
<td>Remote dependency</td>
<td>An instance of parent group depends on one or more instances of the child group being online on any system other than the system on which the parent is online.</td>
</tr>
</tbody>
</table>
Dependency rigidity: soft, firm, or hard dependencies

The type of dependency defines the rigidity of the link between parent and child groups. A soft dependency means minimum constraints, whereas a hard dependency means maximum constraints.

Soft dependency

Specifies the minimum constraints while bringing parent and child groups online. The only constraint is that the child group must be online before the parent group is brought online.

Note that VCS may not honor soft dependencies when either the hastop -local or the /etc/init.d/vcs stop are run. In this scenario, VCS takes both parent and child service groups offline in any order, without considering the group dependency.

For example, in an online local soft dependency, an instance of the child group must be online on the same system before the parent group can come online.

Soft dependency provides the following flexibility:

- If the child group faults, VCS does not immediately take the parent offline. If the child group cannot fail over, the parent remains online.
- When both groups are online, either group, child or parent, may be taken offline while the other remains online.
- If the parent group faults, the child group may remain online.
- When the link is created, the child group need not be online if the parent is online. However, when both groups are online, their online state must not conflict with the type of link.

Firm dependency

Imposes more constraints when VCS brings the parent or child groups online or takes them offline. In addition to the constraint that the child group must be online before the parent group is brought online, the constraints include:

- If the child group faults, the parent is taken offline. If the parent is frozen at the time of the fault, the parent remains in its original state. If the child cannot fail over to another system, the parent remains offline.
- If the parent group faults, the child group may remain online.
- The child group cannot be taken offline if the parent group is online. The parent group can be taken offline while the child is online.
- When the link is created, the parent group must be offline. However, if both groups are online, their online state must not conflict with the type of link.
About service group dependencies

Hard dependency

Imposes the maximum constraints when VCS brings the parent of child service groups online or takes them offline. For example:

- If a child group faults, the parent is taken offline before the child group is taken offline. If the child group fails over, the parent fails over to another system (or the same system for a local dependency). If the child group cannot fail over, the parent group remains offline.
- If the parent faults, the child is taken offline. If the child fails over, the parent fails over. If the child group cannot fail over, the parent group remains offline.

**Note:** When the child faults, if the parent group is frozen, the parent remains online. The faulted child does not fail over.

The following restrictions apply when configuring a hard dependency:

- Only online local hard dependencies are supported.
- Only a single-level, parent-child relationship can be configured as a hard dependency.
- Only one parent and one child group can be configured in a hard dependency.
- Bringing the child group online does not automatically bring the parent online.
- Taking the parent group offline does not automatically take the child offline.
- Bringing the parent online is prohibited if the child is offline.
Dependency limitations

- Multiple parent service groups may depend on a child service group, although a parent group may depend on only one child group.

- A group dependency tree may be at most five levels deep.

- You cannot link two service groups whose current states violate the relationship.
  For example, all link requests are accepted if all instances of parent group are offline.
  All link requests are rejected if parent group is online and child group is offline, except in offline dependencies.
  All online global/online remote link requests to link two parallel groups are rejected.
  All online local link requests to link a parallel parent group to a failover child group are rejected.
Service group dependency configurations

In the following tables, the term instance applies to parallel groups only. If a parallel group is online on three systems, for example, an instance of the group is online on each system. For failover groups, only one instance of a group is online at any time. The default dependency type is Firm.

                        Firm=Yes, but not to system on which child is running.  
                        Soft=Yes, but not to system on which child is running.  
                      - Can child group be switched while parent group is running?  
                        Firm=No  Soft=Yes, but not to system on which parent is running. |
| **Offline local** | - Can parent group be brought online when child group is offline?  
                      Yes.  
                      - Can child group be taken offline when parent group is online?  
                        Yes.  
                      - Can parent group be switched while the child group is running?  
                        Yes, but not to system on which child is running.  
                      - Can child group be switched while the parent group is running?  
                        Yes, but not to system on which parent is running. |
Linking service groups

Note that a configuration may require that a certain service group be running before another service group can be brought online. For example, a group containing resources of a database service must be running before the database application is brought online.

See also “Linking service groups” on page 216

To link service groups from the command line

◆ Type the following command

```
hagrp -link parent_group child_group gd_category
      gd_location gd_type
```

- `parent_group`: Name of the parent group
- `child_group`: Name of the child group
- `gd_category`: Category of group dependency (online/offline).
- `gd_location`: Scope of dependency (local/global/remote).
- `gd_type`: Type of group dependency (soft/firm/hard). Default is firm.

VCS behavior with service group dependencies

VCS enables or restricts service group operations to honor service group dependencies. VCS rejects operations if the operation violates a group dependency.

Online operations in group dependencies

Typically, bringing a child group online manually is never rejected, except under the following circumstances:

- For online local dependencies, if parent is online, a child group online is rejected for any system other than the system where parent is online.
- For online remote dependencies, if parent is online, a child group online is rejected for the system where parent is online.
- For offline local dependencies, if parent is online, a child group online is rejected for the system where parent is online.

The following examples describe situations where bringing a parallel child group online is accepted:
For a parallel child group linked online local with failover/parallel parent, multiple instances of child group online are acceptable.

For a parallel child group linked online remote with failover parent, multiple instances of child group online are acceptable, as long as child group does not go online on the system where parent is online.

For a parallel child group linked offline local with failover/parallel parent, multiple instances of child group online are acceptable, as long as child group does not go online on the system where parent is online.

Offline operations in group dependencies
VCS rejects offline operations if the procedure violates existing group dependencies. Typically, firm dependencies are more restrictive to taking child group offline while parent group is online. Rules for manual offline include:

- Parent group offline is never rejected.
- For all soft dependencies, child group can go offline regardless of the state of parent group.
- For all firm dependencies, if parent group is online, child group offline is rejected.
- For the online local hard dependency, if parent group is online, child group offline is rejected.

Switch operations in group dependencies
Switching a service group implies manually taking a service group offline on one system, and manually bringing it back online on another system. VCS rejects manual switch if the group does not comply with the rules for offline or online operations.
The role of service group dependencies

VCS behavior with service group dependencies
VCS event notification

- About VCS event notification
- Components of VCS event notification
- VCS events and traps
- Monitoring aggregate events
- Configuring notification
About VCS event notification

VCS provides a method for notifying important events such as resource or system faults to administrators or designated recipients. VCS includes a notifier component, which consists of the notifier process and the hanotify utility.

VCS support SNMP consoles that can use an SNMP V2 MIB.

The notifier process performs the following tasks:

- Receives notifications from HAD
- Formats the notification
- Generates an SNMP (V2) trap or sends an email to the designated recipient, or does both.

If you have configured owners for resources, groups, or for the cluster, VCS also notifies owners of events that affect their resources. A resource owner is notified of resource-related events, a group owner of group-related events, and so on.

See “About attributes and their definitions” on page 746.

There are four severity levels: SevereError, Error, Warning, and Information. SevereError indicates the highest severity level, Information the lowest. Note that these severity levels are case-sensitive.

SNMP traps are forwarded to the SNMP console. Typically, traps are predefined for events such as service group or resource faults. You can use the hanotify utility to send additional traps.
Event messages and severity levels

When the VCS engine starts up, it queues all messages as Information. However, when notifier connects, it communicates one of the following severity levels to HAD, depending on which is the lowest:

- lowest severity for SNMP options
- lowest severity for SMTP options

If notifier is started from the command line without specifying a severity level for the SNMP console or SMTP recipients, notifier communicates the default severity level Warning to HAD. If notifier is configured under VCS control, severity must be specified. See the description of the NotifierMngr agent in the Veritas Cluster Server Bundled Agents Reference Guide.

For example, if the following severities are specified for notifier:

- Warning for email recipient 1
- Error for email recipient 2
- SevereError for SNMP console

Notifier communicates the minimum severity, Warning, to HAD, which then queues all messages labelled severity level Warning and greater.

Notifier ensures recipients get only the messages they are designated to receive (according to the specified severity level). However, until notifier communicates the specifications to HAD, HAD stores all messages, because it does not know the severity the user has specified. This behavior prevents messages from being lost between the time HAD stores them and notifier communicates the specifications to HAD.

Persistent and replicated message queue

VCS includes a sophisticated mechanism for maintaining event messages, which ensures that messages are not lost. On each node, VCS queues messages to be sent to the notifier process. This queue is persistent as long as VCS is running and the contents of this queue remain the same on each node. If the notifier service group fails, notifier is failed over to another node in the cluster. Because the message queue is consistent across nodes, notifier can resume message delivery from where it left off even after failover.
How HAD deletes messages

The VCS engine, HAD, stores messages to be sent to notifier. HAD deletes messages under the following conditions:

- The message has been in the queue for one hour and notifier is unable to deliver the message to the recipient. (This behavior means that until notifier connects to HAD, messages are stored permanently in the queue until one of the following conditions are met.)
  
or
- The message queue is full and to make room for the latest message, the earliest message is deleted.
  
or
- VCS receives a message acknowledgement from notifier when notifier has delivered the message to at least one designated recipient.
  
  Example: two SNMP consoles and two email recipients are designated. Notifier sends an acknowledgement to VCS, even if the message reached only one of the four recipients. Error messages are also printed to the log files when delivery errors occur.

Components of VCS event notification

This section describes the notifier process and the hanotify utility.

The notifier process

The notifier process configures how messages are received from VCS and how they are delivered to SNMP consoles and SMTP servers. Using notifier, you can specify notification based on the severity level of the events generating the messages. You can also specify the size of the VCS message queue, which is 30 by default. You can change this value by modifying the MessageQueue attribute. See the Veritas Cluster Server Bundled Agents Reference Guide for more information about this attribute.

When notifier is started from the command line, VCS does not control the notifier process. For best results, use the NotifierMngr agent that is bundled with VCS. Configure notifier as part of a highly available service group, which can then be monitored, brought online, and taken offline. For information about the agent, see the Veritas Cluster Server Bundled Agents Reference Guide.

Note that notifier must be configured in a failover group, not parallel, because only one instance of notifier runs in the entire cluster. Also note that notifier does not respond to SNMP get or set requests; notifier is a trap generator only.
Notifier enables you to specify configurations for the SNMP manager and SMTP server, including machine names, ports, community IDs, and recipients’ email addresses. You can specify more than one manager or server, and the severity level of messages that are sent to each.

**Note:** If you start the notifier outside of VCS control, use the absolute path of the notifier in the command. VCS cannot monitor the notifier process if it is started outside of VCS control using a relative path.

**Example of notifier command**

```
/opt/VRTSvcs/bin/notifier -s m=north -s m=south,p=2000,l=Error,c=your_company
-t m=north,e="abc@your_company.com",l=SevereError
```

In this example, notifier:
- Sends all level SNMP traps to *north* at the default SNMP port and community value *public*.
- Sends Error and SevereError traps to *south* at port 2000 and community value *your_company*.
- Sends SevereError email messages to *north* as SMTP server at default port and to email recipient *abc@your_company.com*. 
The hanotify utility

The hanotify utility enables you to construct user-defined messages. The utility forwards messages to HAD, which stores them in its internal message queue. Along with other messages, user-defined messages are also forwarded to the notifier process for delivery to email recipients, SNMP consoles, or both.

Example of hanotify command

```bash
hanotify -i 1.3.6.1.4.1.1302.3.8.10.2.8.0.10 -l Warning -n agentres -T 7 -t "custom agent" -o 4 -S sys1 -L mv -p sys2 -P mv -c MyAgent -C 7 -O johndoe -m "Custom message"
```

In this example, the number 1.3.6.1.4.1.1302.3.8.10.2.8.0.10 is the OID for the message being sent. Because it is a user-defined message, VCS has no way of knowing the OID associated with the SNMP trap corresponding to this message. Users must provide the OID.

The message severity level is set to Warning. The affected systems are sys1 and sys2. Running this command sends a custom message for the resource agentres from the agent MyAgent.
VCS events and traps

This section lists the events that generate traps, email notification, or both. Note that SevereError indicates the highest severity level, Information the lowest. Traps specific to global clusters are ranked from Critical, the highest severity, to Normal, the lowest.

Events and traps for clusters

<table>
<thead>
<tr>
<th>Event</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster has faulted.</td>
<td>Error</td>
<td>Self-explanatory.</td>
</tr>
<tr>
<td>Heartbeat is down.</td>
<td>Error</td>
<td>The connector on the local cluster lost its heartbeat connection to the remote cluster.</td>
</tr>
<tr>
<td>Remote cluster is in RUNNING state.</td>
<td>Information</td>
<td>Local cluster has complete snapshot of the remote cluster, indicating the remote cluster is in the RUNNING state.</td>
</tr>
<tr>
<td>Heartbeat is “alive.”</td>
<td>Information</td>
<td>Self-explanatory.</td>
</tr>
<tr>
<td>User has logged on to VCS.</td>
<td>Information</td>
<td>A user log on has been recognized because a user logged on by Cluster Manager, or because a \ha.xxxr\ command was invoked.</td>
</tr>
</tbody>
</table>

Events and traps for agents

<table>
<thead>
<tr>
<th>Event</th>

<tr>
<td>Attributes for global service groups are mismatched.</td>
<td>Error</td>
<td>The attributes ClusterList, AutoFailOver, and Parallel are mismatched for the same global service group on different clusters.</td>
</tr>
<tr>
<td>(Global Cluster Option)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
SNMP-specific files

VCS includes two SNMP-specific files: vcs.mib and vcs_trapd, which are created in \%VCS_HOME\%\snmp. The file vcs.mib is the textual MIB for built-in traps that are supported by VCS. Load this MIB into your SNMP console to add it to the list of recognized traps.

The file vcs_trapd is specific to the HP OpenView Network Node Manager (NNM) SNMP console. The file includes sample events configured for the built-in SNMP traps supported by VCS. To merge these events with those configured for SNMP traps:

```
  xnmevents -merge vcs_trapd
```

When you merge events, the SNMP traps sent by VCS by way of notifier are displayed in the HP OpenView NNM SNMP console.

**Note:** For more information on xnmevents, see the HP OpenView documentation.
Trap variables in VCS MIB

Traps sent by VCS are reversible to SNMPv2 after an SNMPv2 -> SNMPv1 conversion.

For reversible translations between SNMPv1 and SNMPv2 trap PDUs, the second-last ID of the SNMP trap OID must be zero. This ensures that once you make a forward translation (SNMPv2 trap -> SNMPv1; RFC 2576 Section 3.2), the reverse translation (SNMPv1 trap --> SNMPv2 trap; RFC 2576 Section 3.1) is accurate.

The VCS notifier follows this guideline by using OIDs with second-last ID as zero, enabling reversible translations.

severityId

This variable indicates the severity of the trap being sent. It can take the following values:

<table>
<thead>
<tr>
<th>Severity Level and Description</th>
<th>Value in Trap PDU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information</td>
<td>0</td>
</tr>
<tr>
<td>Important events exhibiting normal behavior</td>
<td>1</td>
</tr>
<tr>
<td>Warning</td>
<td></td>
</tr>
<tr>
<td>Deviation from normal behavior</td>
<td></td>
</tr>
<tr>
<td>Error</td>
<td>2</td>
</tr>
<tr>
<td>A fault</td>
<td></td>
</tr>
<tr>
<td>Severe Error</td>
<td>3</td>
</tr>
<tr>
<td>Critical error that can lead to data loss or corruption</td>
<td></td>
</tr>
</tbody>
</table>
**entityType and entitySubType**

These variables specify additional information about the entity.

<table>
<thead>
<tr>
<th>Entity Type</th>
<th>Entity Sub-type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource</td>
<td>String. For example, disk.</td>
</tr>

<td>- Resource is not going offline</td>
</tr>
<tr>
<td></td>
<td>- Resource is being restarted by agent</td>
</tr>
<tr>
<td></td>
<td>- Resource went online by itself</td>
</tr>
<tr>
<td></td>
<td>- Resource has faulted</td>
</tr>
<tr>
<td></td>
<td>- Resource health declined</td>
</tr>
<tr>
<td></td>
<td>- Resource health improved</td>
</tr>
<tr>
<td></td>
<td>- Resource is in admin wait state</td>
</tr>
<tr>
<td></td>
<td>- Resource monitor time has changed</td>
</tr>
</tbody>
</table>
### Entity States

<table>
<thead>
<tr>
<th>Entity</th>
<th>States</th>
</tr>
</thead>
</table>
| Service group states    | ■ Service group is online  
                          | ■ Service group is offline  
                          | ■ Service group is auto disabled  
                          | ■ Service group has faulted  
                          | ■ Service group has faulted and cannot be failed over anywhere  
                          | ■ Service group is restarting  
                          | ■ Service group is being switched  
                          | ■ Service group concurrency violation  
                          | ■ Service group is restarting in response to persistent resource going online  
                          | ■ Service group attribute value does not match corresponding remote group attribute value  
                          | ■ Global group concurrency violation  
| System states           | ■ VCS is up on the first node in the Cluster  
                          | ■ VCS is being restarted by hashadow  
                          | ■ VCS is in jeopardy  
                          | ■ VCS has faulted  
                          | ■ A node running VCS has joined cluster  
                          | ■ VCS is up but not in cluster  
                          | ■ VCS has exited manually  
                          | ■ CPU Usage exceeded the threshold on the system  
                          | ■ SWAP Usage exceeded the threshold  
| GCO heartbeat states    | ■ Cluster has lost heartbeat with remote cluster  
                          | ■ Heartbeat with remote cluster is alive  |
Monitoring aggregate events

This section describes how you can detect aggregate events by monitoring individual notifications.

How to detect service group failover

VCS does not send any explicit traps when a failover occurs in response to a service group fault. When a service group faults, VCS generates the following notifications if the AutoFailOver attribute for the service group is set to 1:

- Service Group Fault for the node on which the service group was online and faulted
- Service Group Offline for the node on which the service group faulted
- Service Group Online for the node to which the service group failed over.

How to detect service group switch

When a service group is switched, VCS sends notification to indicate the following events:

- Service group is being switched
- Service Group Offline for the node from which the service group is switched
- Service Group Online for the node to which the service group was switched. This notification is sent after VCS completes the service group switch operation.

Note: You must configure appropriate severity for the notifier to receive these notifications. To receive VCS notifications, the minimum acceptable severity level is Information.
Detecting complementary events

Table 14-1 lists some events that complement each other, or cancel each other out.

<table>
<thead>
<tr>
<th>Event</th>
<th>Cancelling event</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote cluster has faulted. (Global Cluster Option)</td>
<td>Remote cluster is in RUNNING state.</td>
</tr>
<tr>
<td>Heartbeat is down.</td>
<td>Heartbeat is alive.</td>
</tr>
<tr>
<td>Agent is faulted</td>
<td>Agent is restarting</td>
</tr>
<tr>
<td>Resource state is unknown.</td>
<td>Resource went online by itself.</td>
</tr>
<tr>
<td>Health of cluster resource declined.</td>
<td>Health of cluster resource improved.</td>
</tr>
<tr>
<td>VCS has faulted.</td>
<td>A node running VCS has joined cluster.</td>
</tr>
<tr>
<td>Service group has faulted.</td>
<td>Service group is online.</td>
</tr>
<tr>
<td>Service group is offline.</td>
<td>Service group is online</td>
</tr>
<tr>
<td>Service group is being switched.</td>
<td>Service group is online</td>
</tr>
</tbody>
</table>

Configuring notification

Configuring notification involves creating a resource for the Notifier Manager (NotifierMngr) agent in the ClusterService group. See the Veritas Cluster Server Bundled Agents Reference Guide for more information about the agent.

VCS provides several methods for configuring notification:

- Manually editing the main.cf file.
- Using the Notifier wizard.
  See “Setting up VCS event notification using the Notifier wizard” on page 250.
Chapter 15

VCS event triggers

- About VCS event triggers
- Using event triggers
- List of event triggers
About VCS event triggers

Triggers let you invoke user-defined scripts for specified events in a cluster. VCS determines if the event is enabled and invokes the hatrigger script. The script is located at:

%VCS_HOME%\bin\hatrigger.pl

VCS also passes the name of the event trigger and associated parameters. For example, when a service group comes online on a system, VCS invokes the following command:

hatrigger -postonline system service_group.

VCS does not wait for the trigger to complete execution. VCS calls the trigger and continues normal operation.

VCS invokes event triggers on the system where the event occurred, with the following exceptions:

- VCS invokes the sysoffline and nofailover event triggers on the lowest-numbered system in the RUNNING state.
- VCS invokes the violation event trigger on all systems on which the service group was brought partially or fully online.

Using event triggers

VCS provides a sample Perl script for each event trigger at the following location:

%VCS_HOME%\bin\sample_triggers

Customize the scripts according to your requirements: you may choose to write your own Perl scripts.

To use an event trigger

1. Use the sample scripts to write your own custom actions for the trigger.
2. Move the modified trigger script to the following path on each node:
   %VCS_HOME%\bin\triggers
3. Configure other attributes that may be required to enable the trigger. See the usage information for the trigger for more information.

See “List of event triggers” on page 553.
List of event triggers

The information in the following sections describes the various event triggers, including their usage, parameters, and location.

cpuusage event trigger

Description

The cpuusage event trigger is invoked when the system's CPU usage exceeds the ActionThreshold value of the system's CPUUsageMonitoring attribute for a duration longer than the ActionTimeLimit value. The trigger is not invoked if it was invoked on the system within the last five minutes.

See “When a resource comes online” on page 664.

This event trigger is configurable.

Usage

- cpuusage  
  - **triggertype** system cpu_usage

  - **triggertype**—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).

  If 0, the trigger is invoked from:
  
  %VCS_HOME%\bin\triggers\CPUUSage.extension (.exe, .pl,. ksh, or .bat)

  If 1, the system reboots by invoking the trigger from:
  
  %VCS_HOME%\bin\internal_triggers\cpuusage.pl.

  - **system**—represents the name of the system.

  - **cpu_usage**—represents the percentage of CPU utilization on the system.

To enable the trigger

Set following values in the system's CPUUsageMonitoring attribute:

- **Enabled** = 1
- **ActionTimeLimit** = Non-zero value representing time in seconds.
- **ActionThreshold** = Non-zero value representing CPU percentage utilization.
- **Action** = CUSTOM or REBOOT.

  - **CUSTOM**—Invokes trigger from:
  
  %VCS_HOME%\bin\triggers\CPUUSage.extension (.exe, .pl, ksh, or .bat)

  - **REBOOT**—invokes trigger from:
  
  %VCS_HOME%\bin\internal_triggers\cpuusage.pl.

  and the system reboots.

To disable the trigger

Set one of the following values in CPUUsageMonitoring system attribute to 0 for the system:

- **ActionTimeLimit** = 0
- **ActionThreshold** = 0
injeopardy event trigger

Description  Invoked when a system is in jeopardy. Specifically, this trigger is invoked when a system has only one remaining link to the cluster, and that link is a network link (LLT). This event is a considered critical because if the system loses the remaining network link, VCS does not fail over the service groups that were online on the system. Use this trigger to notify the administrator of the critical event. The administrator can then take appropriate action to ensure that the system has at least two links to the cluster.

This event trigger is non-configurable.

Usage  
- injeopardy  
  triggertype system system_state

  - triggertype—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
    For this trigger, triggertype=0.
  - system—represents the name of the system.
  - system_state—represents the value of the State attribute.
loadwarning event trigger

**Description** Invoked when a system becomes overloaded because the load of the system's online groups exceeds the system's LoadWarningLevel attribute for an interval exceeding the LoadTimeThreshold attribute.

For example, say the Capacity is 150, the LoadWarningLevel is 80, and the LoadTimeThreshold is 300. Also, the sum of the Load attribute for all online groups on the system is 135. Because the LoadWarningLevel is 80, safe load is 0.80*150=120. Actual system load is 135. If system load stays above 120 for more than 300 seconds, the LoadWarningLevel trigger is invoked.

Use this trigger to notify the administrator of the critical event. The administrator can then switch some service groups to another system, ensuring that no one system is overloaded.

This event trigger is non-configurable.

**Usage**

```
loadwarning triggertype system available_capacity
```

- **triggertype**—represents whether trigger is custom (triggertype=0) or internal (triggertype=1). For this trigger, triggertype=0.
- **system**—represents the name of the system.
- **available_capacity**—represents the system's AvailableCapacity attribute. (AvailableCapacity=Capacity-sum of Load for system's online groups.)
nfs_postoffline event trigger

**Description**  Restarts the following daemons after the group goes offline:
- nfsd
- mountd
- lockd
- statd
- nfsrgyd
  When you set a value for the NFS agent's NFSv4Root attribute, restarts the nfsrgyd daemon.
- gssd
  When you set a value of 1 for the NFS agent's NFSSecurity attribute, restarts the gssd daemon.

**Usage**  
- nfs_postoffline  
  triggertype  system  service_group

  - triggertype—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
  - For this trigger, triggertype=0.
  - system—represents the name of the last system on which an attempt was made to online the service group.
  - service_group—represents the name of the service group.

nfs_preonline event trigger

**Description**  Terminates the following daemons when the value of the NFSRestart agent's NFLockFailover attribute is 1.
- statd
- lockd

**Usage**  
- nfs_preonline  
  triggertype  system  service_group

  - triggertype—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
  - For this trigger, triggertype=0.
  - system—represents the name of the last system on which an attempt was made to online the service group.
  - service_group—represents the name of the service group.
nofailover event trigger

**Description**  Called from the lowest-numbered system in **RUNNING** state when a service group cannot fail over.

This event trigger is non-configurable.

**Usage**

- nofailover  

  ```
  trigger_type  system  service_group
  ```

  - `trigger_type`—represents whether trigger is custom (`trigger_type=0`) or internal (`trigger_type=1`).
    For this trigger, `trigger_type=0`.
  - `system`—represents the name of the last system on which an attempt was made to online the service group.
  - `service_group`—represents the name of the service group.

postoffline event trigger

**Description**  This event trigger is invoked on the system where the group went offline from a partial or fully online state. This trigger is invoked when the group faults, or is taken offline manually.

This event trigger is non-configurable.

**Usage**

- postoffline  

  ```
  trigger_type  system  service_group
  ```

  - `trigger_type`—represents whether trigger is custom (`trigger_type=0`) or internal (`trigger_type=1`).
    For this trigger, `trigger_type=0`.
  - `system`—represents the name of the system.
  - `service_group`—represents the name of the service group that went offline.

postonline event trigger

**Description**  This event trigger is invoked on the system where the group went online from an offline state.

This event trigger is non-configurable.
### Usage

- `postonline` `triggertype` `system` `service_group`

- **triggertype**—represents whether trigger is custom (`triggertype=0`) or internal (`triggertype=1`). For this trigger, `triggertype=0`.

- **system**—represents the name of the system.

- **service_group**—represents the name of the service group that went online.
preonline event trigger

**Description** Indicates that when the HAD should call a user-defined script before bringing a service group online in response to the hagrp -online command or a fault.

If the trigger does not exist, VCS continues to bring the group online. If the script returns 0 without an exit code, VCS runs the hagrp -online -nopre command, with the -checkpartial option if appropriate.

If you do want to bring the group online, define the trigger to take no action. This event trigger is configurable.

**Usage**

```
-preonline triggertype system service_group whyonline [system_where_group_faulted]
```

- **triggertype**—represents whether trigger is custom (triggertype=0) or internal (triggertype=1). For this trigger, triggertype=0.
- **system**—represents the name of the system.
- **service_group**—represents the name of the service group on which the hagrp command was issued or the fault occurred.
- **whyonline**—represents two values:
  - **FAULT**: Indicates that the group was brought online in response to a group failover or switch.
  - **MANUAL**: Indicates that group was brought online manually on the system that is represented by the variable system.
- **system_where_group_faulted**—represents the name of the system on which the group has faulted or switched. This variable is optional and set when the engine invokes the trigger during a failover or switch.

**To enable the trigger**

Set the PreOnline attribute in the service group definition to 1. You can set a local (per-system) value for the attribute to control behavior on each node in the cluster.

**To disable the trigger**

Set the PreOnline attribute in the service group definition to 0. You can set a local (per-system) value for the attribute to control behavior on each node in the cluster.
preonline_ipc event trigger

**Description**
Performs the following actions before a service containing IP resources is brought online:

- Verifies that IP addresses configured for IP resources in the service group are not online anywhere else. If a configured IP address is online somewhere else, the trigger waits for 5 seconds. If the configured IP is online after 5 seconds, the trigger aborts the online operation for the IP resource.
- Verifies that the node is not isolated from other nodes in the cluster by pinging the broadcast address and checking the heartbeat links. If the trigger does not find any heartbeat links and the broadcast ping fails, the trigger aborts the online operation to prevent possible split brain condition.

**Usage**
- `preonline` `triggertype` `system` `service_group` `whyonlining` `[system_where_group_faulted]`

  - `triggertype`—represents whether trigger is custom (`triggertype=0`) or internal (`triggertype=1`). For this trigger, `triggertype=0`.
  - `system`—represents the name of the system.
  - `service_group`—represents the name of the service group on which the `hagrp` command was issued or the fault occurred.
  - `whyonlining`—represents two values:
    - `FAULT`: Indicates that the group was brought online in response to a group failover or switch.
    - `MANUAL`: Indicates that group was brought online manually on the system that is represented by the variable `system`.
  - `system_where_group_faulted`—represents the name of the system on which the group has faulted or switched. This variable is optional and set when the engine invokes the trigger during a failover or switch.

**Note:** To use this trigger, copy the `preonline_ipc` script from `$VCS_HOME/bin/sample_triggers` to `$VCS_HOME/bin/triggers/` and rename the script to `preonline`. If you use the `preonline` trigger for other purposes, merge the contents of the `preonline_ipc` script with those of the `preonline` script.

**To enable the trigger**
Set the PreOnline attribute in the service group definition to 1.
You can set a local (per-system) value for the attribute to control behavior on each node in the cluster.

**To disable the trigger**
Set the PreOnline attribute in the service group definition to 0.
You can set a local (per-system) value for the attribute to control behavior on each node in the cluster.
resadminwait event trigger

**Description**
Invoked when a resource enters `ADMIN_WAIT` state.

When VCS sets a resource in the `ADMIN_WAIT` state, it invokes the resadminwait trigger according to the reason the resource entered the state.

See “Clearing resources in the `ADMIN_WAIT` state” on page 481.

This event trigger is non-configurable.

**Usage**
```
-resadminwait system resource adminwait_reason
```
- `system`—represents the name of the system.
- `resource`—represents the name of the faulted resource.
- `adminwait_reason`—represents the reason the resource entered the `ADMIN_WAIT` state. Values range from 0-5:
  0 = The offline function did not complete within the expected time.
  1 = The offline function was ineffective.
  2 = The online function did not complete within the expected time.
  3 = The online function was ineffective.
  4 = The resource was taken offline unexpectedly.
  5 = The monitor function consistently failed to complete within the expected time.
resfault event trigger

**Description** Invoked on the system where a resource has faulted. Note that when a resource is faulted, resources within the upward path of the faulted resource are also brought down.

This event trigger is configurable.

To configure this trigger, you must define the following:

TriggerResFault: Set the attribute to 1 to invoke the trigger when a resource faults.

**Usage**

```
resfault triggertype system resource previous_state
```

- **triggertype**—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
  - For this trigger, triggertype=0.
- **system**—represents the name of the system.
- **resource**—represents the name of the faulted resource.
- **previous_state**—represents the resource's previous state.

**To enable the trigger** To invoke the trigger when a resource faults, set the TriggerResFault attribute to 1.
resnotoff event trigger

**Description**  Invoked on the system if a resource in a service group does not go offline even after issuing the offline command to the resource.

When invoked, the trigger script waits for a predefined interval and checks the state of the resource. If the resource is not offline, the trigger issues a system shutdown command, followed by the command `hastop -local -evacuate`.

This event trigger is configurable.

To configure this trigger, you must define the following:

**Resource Name** Define resources for which to invoke this trigger by entering their names in the following line in the script: `@resources = ("resource1","resource2");`

If any of these resources do not go offline, the trigger is invoked with that resource name and system name as arguments to the script.

**$shutdown_timeout** Define the time the script waits before it checks the resource state and issues a system shutdown command. For example, if this variable is set to 300, the script waits for 300 seconds before checking that the resource is offline and issuing the shutdown command.

**$shutdown_countdown** Define the time the script waits to shut down the system after issuing the `hastop -local -evacuate` command. For example, the value 300 indicates that the script waits for 300 seconds after issuing the `hastop -local -evacuate` command, and then shuts down the system.

Define this value to be greater than the time required to switch all service groups on the system to another system.

**$forced_close_app** Define whether the script forcefully closes all running applications when it triggers the system shutdown command. The value 1 indicates the script forcefully closes all running applications. The value 0 indicates it does not. Default is 1.

**$reboot_option** Define whether the script reboots the system after issuing the system shutdown command. The value 1 indicates the script reboots the system. The value 0 indicates it does not. Default is 1.

**Usage**  
- resnotoff triggertype system resource

- **triggertype**—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
  
  For this trigger, triggertype=0.

- **system**—represents the system on which the resource is not going offline.

- **resource**—represents the name of the resource.
resstatechange event trigger

Description
This trigger is invoked under the following conditions:

- Resource goes from OFFLINE to ONLINE.
- Resource goes from ONLINE to OFFLINE.
- Resource goes from ONLINE to FAULTED.
- Resource goes from FAULTED to OFFLINE. (When fault is cleared on non-persistent resource.)
- Resource goes from FAULTED to ONLINE. (When faulted persistent resource goes online or faulted non-persistent resource is brought online outside VCS control.)
- Resource is restarted by an agent because resource faulted and RestartLimit was greater than 0.

This event trigger is configurable.

Usage
- resstatechange triggertype system resource previous_state new_state

triggertype—represents whether trigger is custom (triggertype=0) or internal (triggertype=1).
For this trigger, triggertype=0.

system—represents the name of the system.

resource—represents the name of the resource.

previous state—represents the resource's previous state.

new state—represents the resource's new state.

To enable the trigger
This event trigger is not enabled by default. You must enable resstatechange by setting the attribute TriggerResStateChange to 1 in the main.cf file, or by issuing the command:

hagrp -modify service_group TriggerResStateChange 1

Note: Use the resstatechange trigger carefully. For example, enabling this trigger for a service group with 100 resources means 100 hatrigger processes and 100 resstatechange processes are fired each time the group is brought online or taken offline. Also, this is not a "wait-mode trigger. Specifically, VCS invokes the trigger and does not wait for trigger to return to continue operation.
sysoffline event trigger

**Description** Called from the lowest-numbered system in **RUNNING** state when a system leaves the cluster.

This event trigger is non-configurable.

**Usage**

- `sysoffline  system  system_state`
  - **system**—represents the name of the system.
  - **system_state**—represents the value of the State attribute.

See “System states” on page 740.

sysup event trigger

**Description** Called when the first system comes up in the cluster

This event trigger is configurable.

**Usage**

- `sysup  triggertype  system  system_state`
  - **triggertype**—represents whether trigger is custom (`triggertype=0`) or internal (`triggertype=1`).
    
    For this trigger, `triggertype=0`.
  - **system**—represents the name of the system.
  - **system_state**—state of the system (**RUNNING** in this case)

See “System states” on page 740.
sysjoin event trigger

**Description**
Called when a new system joins the cluster. The trigger is invoked on all nodes in the cluster.
This event trigger is configurable.

**Usage**
- `sysjoin triggertype system system_state`
  - `triggertype`—represents whether trigger is custom (`triggertype=0`) or internal (`triggertype=1`).
  - For this trigger, `triggertype=0.system`—represents the name of the system.
  - `system_state`—represents the value of the State attribute.
  See “System states” on page 740.

unable_to_restart_agent event trigger

**Description**
This trigger is invoked when an agent faults more than a predetermined number of times with in an hour. When this occurs, VCS gives up trying to restart the agent. VCS invokes this trigger on the node where the agent faults.
You can use this trigger to notify the administrators that an agent has faulted, and that VCS is unable to restart the agent. The administrator can then take corrective action.

**Usage**
- `unable_to_restart_agent system resource_type`
  - `system`—represents the name of the system.
  - `resource_type`—represents the resource type associated with the agent.

**To disable the trigger**
Remove the files associated with the trigger from the `$VCS_HOME/bin/triggers` directory.
unable_to_restart_had event trigger

**Description**  This event trigger is invoked by hashadow when hashadow cannot restart HAD on a system. If HAD fails to restart after six attempts, hashadow invokes the trigger on the system.

The default behavior of the trigger is to reboot the system. However, service groups previously running on the system are autodisabled when hashadow fails to restart HAD. Before these service groups can be brought online elsewhere in the cluster, you must autoenable them on the system. To do so, customize the unable_to_restart_had trigger to remotely execute the following command from any node in the cluster where VCS is running:

```bash
hagrp -autoenable service_group -sys system
```

For example, if hashadow fails to restart HAD on system1, and if group1 and group2 were online on that system, a trigger customized in this manner would autoenable group1 and group2 on system1 before rebooting. Autoenabling group1 and group2 on system1 enables these two service groups to come online on another system when the trigger reboots system1.

This event trigger is non-configurable.

**Usage**

- `unable_to_restart_had`

This trigger has no arguments.

violation event trigger

**Description**  This trigger is invoked only on the system that caused the concurrency violation. Specifically, it takes the service group offline on the system where the trigger was invoked. Note that this trigger applies to failover groups only. The default trigger takes the service group offline on the system that caused the concurrency violation.

This event trigger is non-configurable.

**Usage**

- `violation system service_group`

  - `system`—represents the name of the system.
  - `service_group`—represents the name of the service group that was fully or partially online.
VCS event triggers

List of event triggers
Cluster configurations for disaster recovery

Connecting clusters—Creating global clusters

- How VCS global clusters work
- VCS global clusters: The building blocks
- Prerequisites for global clusters
- Setting up a global cluster
- When a cluster faults
- Setting up a fire drill
- Multi-tiered application support using the RemoteGroup agent in a global environment
- Test scenario for a multi-tiered environment
How VCS global clusters work

Local clustering provides local failover for each site or building. But, these configurations do not provide protection against large-scale disasters such as major floods, hurricanes, and earthquakes that cause outages for an entire city or region. The entire cluster could be affected by an outage.

In such situations, VCS global clusters ensure data availability by migrating applications to remote clusters located considerable distances apart.

Let us take the example of an Oracle database configured in a VCS global cluster. Oracle is installed and configured in both clusters. Oracle data is located on shared disks within each cluster and is replicated across clusters to ensure data concurrency. The Oracle service group is online on a system in cluster A and is configured to fail over globally, on clusters A and B.

Figure 16-1 Sample global cluster setup

VCS continuously monitors and communicates events between clusters. Intercluster communication ensures that the global cluster is aware of the state of the service groups that are configured in the global cluster at all times.

In the event of a system or application failure, VCS fails over the Oracle service group to another system in the same cluster. If the entire cluster fails, VCS fails over the service group to the remote cluster, which is part of the global cluster. VCS also redirects clients once the application is online on the new location.
VCS global clusters: The building blocks

VCS extends clustering concepts to wide-area high availability and disaster recovery with the following:

- Visualization of remote cluster objects
- Global service groups
- Global cluster management
- Serialization—The Authority attribute
- Resiliency and “Right of way”
- VCS agents to manage wide-area failover
- The Steward process: Split-brain in two-cluster global clusters

Visualization of remote cluster objects

VCS enables you to visualize remote cluster objects using the VCS command-line, the Java Console, and VCS Management Console.

You can define remote clusters in your configuration file, main.cf. The Remote Cluster Configuration wizard provides an easy interface to do so. The wizard updates the main.cf files of all connected clusters with the required configuration changes.

See “Adding a remote cluster” on page 623.

Global service groups

A global service group is a regular VCS group with additional properties to enable wide-area failover. The global service group attribute ClusterList defines the list of clusters to which the group can fail over. The service group must be configured on all participating clusters and must have the same name on each cluster. The Global Group Configuration wizard provides an easy interface to configure global groups.

See “Administering global service groups” on page 630.
Global cluster management

VCS enables you to perform operations (online, offline, switch) on global service groups from any system in any cluster. You must log on with adequate privileges for cluster operations.

See “User privileges in global clusters” on page 71.

You can bring service groups online or switch them to any system in any cluster. If you do not specify a target system, VCS uses the FailOverPolicy to determine the system.

See “Defining failover policies” on page 478.

Management of remote cluster objects is aided by inter-cluster communication enabled by the wide-area connector (wac) process.

Wide-area connector process

The wide-area connector (wac) is a failover Process resource that ensures communication between clusters.

The wac process runs on one system in each cluster and connects with peers in remote clusters. It receives and transmits information about the status of the cluster, service groups, and systems. This communication enables VCS to create a consolidated view of the status of all the clusters configured as part of the global cluster. The process also manages wide-area heartbeating to determine the health of remote clusters. The process also transmits commands between clusters and returns the result to the originating cluster.

VCS provides the option of securing the communication between the wide-area connectors.

See “Secure communication in global clusters” on page 578.
Wide-area heartbeats
The wide-area Heartbeat agent manages the inter-cluster heartbeat. Heartbeats are used to monitor the health of remote clusters.
See “Heartbeat attributes (for global clusters)” on page 794.
You can change the default values of the heartbeat agents using the command `hahb -modify`.

Serialization–The Authority attribute
VCS ensures that multi-cluster service group operations are conducted serially to avoid timing problems and to ensure smooth performance. The Authority attribute prevents a service group from coming online in multiple clusters at the same time. Authority is a persistent service group attribute and it designates which cluster has the right to bring a global service group online. The attribute cannot be modified at runtime.
If two administrators simultaneously try to bring a service group online in a two-cluster global group, one command is honored, and the other is rejected based on the value of the Authority attribute.
The attribute prevents bringing a service group online in a cluster that does not have the authority to do so. If the cluster holding authority is down, you can enforce a takeover by using the command `hagrp -online -force service_group`. This command enables you to fail over an application to another cluster when a disaster occurs.

**Note:** A cluster assuming authority for a group does not guarantee the group will be brought online on the cluster. The attribute merely specifies the right to attempt bringing the service group online in the cluster. The presence of Authority does not override group settings like frozen, autodisabled, non-probed, and so on, that prevent service groups from going online.

You must seed authority if it is not held on any cluster.
Offline operations on global groups can originate from any cluster and do not require a change of authority to do so, because taking a group offline does not necessarily indicate an intention to perform a cross-cluster failover.

Authority and AutoStart
The attributes Authority and AutoStart work together to avoid potential concurrency violations in multi-cluster configurations.
If the AutoStartList attribute is set, and if a group’s Authority attribute is set to 1, the VCS engine waits for the wac process to connect to the peer. If the connection fails, it means the peer is down and the AutoStart process proceeds.
If the connection succeeds, HAD waits for the remote snapshot. If the peer is holding the authority for the group and the remote group is online (because of takeover), the local cluster does not bring the group online and relinquishes authority.

If the Authority attribute is set to 0, AutoStart is not invoked.

**Resiliency and “Right of way”**

VCS global clusters maintain resiliency using the wide-area connector process and the ClusterService group. The wide-area connector process runs as long as there is at least one surviving node in a cluster.

The wide-area connector, its alias, and notifier are components of the ClusterService group.

**VCS agents to manage wide-area failover**

VCS agents now manage external objects that are part of wide-area failover. These objects include replication, DNS updates, and so on. These agents provide a robust framework for specifying attributes and restarts, and can be brought online upon fail over.
### The Steward process: Split-brain in two-cluster global clusters

Failure of all heartbeats between any two clusters in a global cluster indicates one of the following:

- The remote cluster is faulted.
- All communication links between the two clusters are broken.

In global clusters with more than three clusters, VCS queries the connected clusters to confirm that the remote cluster is truly down. This mechanism is called *inquiry*.

In a two-cluster setup, VCS uses the *Steward* process to minimize chances of a wide-area split-brain. The process runs as a standalone binary on a system outside of the global cluster configuration.

When all communication links between any two clusters are lost, each cluster contacts the Steward with an inquiry message. The Steward sends an ICMP ping to the cluster in question and responds with a negative inquiry if the cluster is running or with positive inquiry if the cluster is down. The Steward can also be used in configurations with more than two clusters.

VCS provides the option of securing communication between the Steward process and the wide-area connectors.

See "Secure communication in global clusters" on page 578.

A Steward is effective only if there are independent paths from each cluster to the host that runs the Steward. If there is only one path between the two clusters, you must prevent split-brain by confirming manually via telephone or some messaging system with administrators at the remote site if a failure has occurred. By default, VCS global clusters fail over an application across cluster boundaries with administrator confirmation. You can configure automatic failover by setting the ClusterFailOverPolicy attribute to Auto.

See "Administering the cluster from the Cluster Management Console" on page 105.
The default port for the steward is 14156.

Secure communication in global clusters

In global clusters, VCS provides the option of making the following communications secure:

- Communication between the wide-area connectors.
- Communication between the wide-area connectors and the Steward process.

For secure authentication, the wide-area connector process gets a security context as an account in the local authentication broker on each cluster node.

The WAC account belongs to the same domain as HAD and Command Server and is specified as:

```plaintext
name = _WAC_GCO_({systemname})
domain = HA_SERVICES@{fully_qualified_system_name}
```

You must configure the wide-area connector process in all clusters to run in secure mode. If the wide-area connector process runs in secure mode, you must run the Steward in secure mode.

See “Configuring the Steward process (optional)” on page 588.
See “Prerequisites for clusters running in secure mode” on page 580.
Prerequisites for global clusters

This section describes the prerequisites for configuring global clusters.

Cluster setup

You must have at least two clusters to set up a global cluster. Every cluster must have the required licenses. A cluster can be part of one global cluster. VCS supports a maximum of four clusters participating in a global cluster.

Clusters must be running on the same platform. The operating system versions must also be the same. Clusters must be using the same VCS version.

Cluster names must be unique within each global cluster; system and resource names need not be unique across clusters. Service group names need not be unique across clusters; however, global service groups must have identical names.

Every cluster must have a valid virtual IP address, which is tied to the cluster. Define this IP address in the cluster’s ClusterAddress attribute. This address is normally configured as part of the initial VCS installation. The IP address must have a DNS entry.

All clusters in a global cluster must use either IPv4 or IPv6 addresses. VCS does not support configuring clusters that use different Internet Protocol versions in a global cluster.

For remote cluster operations, you must configure a VCS user with the same name and privileges in each cluster.

See “User privileges in global clusters” on page 71.

Application setup

Applications to be configured as global groups must be configured to represent each other in their respective clusters. The multiple application groups of a global group must have the same name in each cluster. The individual resources of the groups can be different. For example, one group might have a MultiNIC resource or more Mount-type resources. Client systems redirected to the remote cluster in case of a wide-area failover must be presented with the same application they saw in the primary cluster.

However, the resources that make up a global group must represent the same application from the point of the client as its peer global group in the other cluster. Clients redirected to a remote cluster should not be aware that a cross-cluster failover occurred, except for some downtime while the administrator initiates or confirms the failover.
Wide-area heartbeats
There must be at least one wide-area heartbeat going from each cluster to every other cluster. VCS starts communicating with a cluster only after the heartbeat reports that the cluster is alive. VCS uses the ICMP ping by default, the infrastructure for which is bundled with the product. VCS configures the ICMP heartbeat if you use Cluster Manager (Java Console) to set up your global cluster. Other heartbeats must be configured manually.

ClusterService group
The ClusterService group must be configured with the Process (for the wide-area connector), NIC, and IP resources. The service group may contain additional resources for Cluster Management Console and notification, if these components are configured. It is configured automatically when VCS is installed or upgraded.

Replication setup
VCS global clusters are used for disaster recovery, so you must set up real-time data replication between clusters. You can use VCS agents for supported replication solutions to manage the replication.

Prerequisites for clusters running in secure mode
If you plan to configure secure communication among clusters in the global clusters, then you must meet the following prerequisites:

- For both clusters to communicate in secure mode, both clusters must share a root broker or the root brokers must share a trust relationship.
- Both clusters must run in secure mode.
- If you plan to secure the communication between the wide-area connector processes, you must configure the processes in both clusters to run in secure mode.
- If the wide-area connector process runs in secure mode, you must run the Steward in secure mode.

Setting up a global cluster
This section describes the steps for planning, configuring, and testing a global cluster. It describes an example of converting a single instance Oracle database configured for local high availability in a VCS cluster to a highly available,
disaster-protected infrastructure using a second cluster. The solution uses Veritas Volume Replicator to replicate data.

In this example, a single-instance Oracle database is configured as a VCS service group (appgroup) on a two-node cluster.

Note: Before beginning the process, review the prerequisites listed in the section “Prerequisites for global clusters” on page 579 and make sure your configuration is ready for a global cluster application.

The process involves the following steps:

- Preparing the application for the global environment
- Configuring the ClusterService group
- Configuring replication resources in VCS
- Linking the application and replication service groups
- Configuring the second cluster
- Linking clusters
- Configuring the Steward process (optional)
- Configuring the global service group

Preparing the application for the global environment

Perform the following tasks to set up a global cluster environment.
To prepare the application for the global cluster environment

1. Install the application (Oracle in this example) in the second cluster. Make sure the installation is identical with the one in the first cluster.

2. Set up replication between the shared disk groups in both clusters. If your configuration uses VVR, the process involves grouping the shared data volumes in the first cluster into a Replicated Volume Group (RVG), and creating the VVR Secondary on hosts in the new cluster, located in your remote site. See Veritas Volume Replicator documentation.

Configuring the ClusterService group

You can configure the service group using the VCS Configuration wizard, Cluster Manager (Java Console), or the command line. For instructions on how to create the service group using the wizard, see “Configuring the ClusterService group” on page 445.

To configure the ClusterService group

1. If the ClusterService group does not exist in the cluster create a new service group called ClusterService.

2. Add resources of type IP, NIC, and Process to the service group.

3. Name the NIC resource csgnic and configure the following attribute for the resource:
   - MACAddress—The physical address of the adapter on the system. This attribute has a per-system value.

4. Name the IP resource webip and configure the following attributes for the resource:
   - MACAddress—The physical address of the adapter on the system. This attribute could have a per-system value.
   - Address—The virtual IP address for communicating between clusters. The IP address must have a DNS entry.
   - SubNetMask—The subnet mask associated with the virtual IP address.

5. Name the Process resource wac and configure the following attributes for the resource:
   - StartProgram—Complete path to the wide-area connector process.
     - If the clusters are running in secure mode, you can set this attribute to: %VCS_HOME%\bin\wac.exe -secure. For example: C:\Program Files\VERITAS\Cluster Server\bin\wac.exe -secure.
Connecting clusters—Creating global clusters

Setting up a global cluster

- If the clusters are not running in secure mode, set this attribute to:
  \%VCS_HOME%\bin\wac.exe
  For example: C:\Program Files\VERITAS\Cluster Server\bin\wac.exe.
- StopProgram—Complete path to the program that stops the wac process. Set this attribute to: \%VCS_HOME%\bin\wacstop.exe
  For example: C:\Program Files\VERITAS\Cluster Server\bin\wacstop.exe.
- MonitorProgram—Complete path to the program that monitors the wac process, typically C:\Program Files\VERITAS\Cluster Server\bin\wacmonitor.exe.

6 Mark the wac resource as critical.
7 Set resource dependencies as per the following information:
   - Process resource (wac) depends on the IP resource (webip)
   - IP resource (webip) depends on the NIC resource (csgnic)

  Enable the resources and bring the ClusterService group online.

Configuring replication resources in VCS

This section describes how to set up replication using Veritas Volume Replicator (VVR.)

VCS supports several replication solutions for global clustering. Contact your Symantec sales representative for the solutions that VCS supports.

Prerequisites

- Create Replicator Log Volumes for the primary and secondary sites.
- Create the replicated data sets for VVR. See the VVR documentation for instructions.
- Verify that the disk group is imported on the node on which you want to create the VVR RVG Service Group.
- Verify VCS is running, by running the following command on the host on which the you intend to run the VVR configuration Wizard.

To create a VVR service group

1 From the active node of the cluster at the primary site, click **Start > All Programs > Symantec > Veritas Cluster Server > Configuration Tools > Volume Replicator Agent Configuration Wizard** to launch the configuration wizard.
2 Read and verify the requirements on the Welcome panel, and click **Next**.

3 In the Wizard Options panel, click **Create a new replication service group** and then click **Next**.

4 Specify the service group name and system priority list:
   - Enter the service group name.
   - In the Available Cluster Systems box, click the nodes on which to configure the service group, and click the right-arrow icon to move the nodes to the service group's system list. Make sure that the set of nodes selected for the replication service group is the same or a superset of nodes selected for the application's Server service group. Ensure that the nodes are in the same priority order.
   - To remove a node from the service group's system list, click the node in the Systems in Priority Order box, and click the left arrow icon.
   - To change the priority of a node in the system list, click the node in the Systems in Priority Order box, then click the up and down arrow icons. The node at the top of the list has the highest priority.
   - Click **Next**.

5 A message appears, indicating that the configuration will be changed from Read Only to Read/Write. Click **Yes** to continue.

6 In the Disk Group and Replicated Volume Group Configuration panel:
   - Select **Configure RVGPrimary resource for selected RVG**.
   - Select the replicated volume group for which you want to configure the VVR RVG resource.
   - Click **Next**.

7 In the IP Resource Options panel, select **Create a new IP resource** and click **Next**.

8 Enter the network information:
   - Verify or enter the virtual IP address; use the IP address specified as the primary IP address when you configured the RDS.
   - Verify the subnet mask.
   - Specify the adapters for each system in the configuration.
   - Click **Next**.

   **Note:** At this step, the specified IP address does not yet need to exist.

9 If a message appears, indicating that the specified IP is not configured for replication in this RVG, click **OK** to continue.
10. Review the summary of the service group configuration:
The Resources box lists the configured resources. Click a resource to view its attributes and their configured values in the Attributes box.

- If necessary, change the resource names; the wizard assigns unique names to resources based on their respective name rules.
  To edit a resource name, click the resource name and modify it in the right pane. Press Enter after editing each attribute. To cancel editing a resource name, press Esc.

- Click Next to create the VVR service group.

11. When prompted, click Yes to create the service group.
Click Finish to bring the replication service group online.

Linking the application and replication service groups
Set an online local hard group dependency from appgroup to appgroup_rep to ensure that the service groups fail over and switch together.

To link the application and replication service groups
1. In the Cluster Explorer configuration tree, click the cluster name.
2. In the view panel, click the Service Groups tab. This opens the service group dependency graph.
3. Click Link.
4. Click the parent group, appgroup, and move the mouse toward the child group, appgroup_rep.
5. Click the child group appgroup_rep.
6. In the Link Service Groups dialog box, click the online local relationship and the hard dependency type and click OK.

Configuring the second cluster
1. Modify the ClusterService group in the second cluster for global cluster configuration.
   See “Configuring the ClusterService group” on page 582.

2. Create a configuration that is similar to the one in the first cluster.
   You can do this by either using Cluster Manager (Java Console) to copy and paste resources from the primary cluster, or by copying the configuration of the appgroup and appgroup_rep groups from the main.cf file in the primary cluster to the secondary cluster.
   Run the VVR Configuration wizard to set up the VVR service group.
3 To assign remote administration privileges to users, configure users with
the same name and privileges on both clusters.
See “User privileges in global clusters” on page 71.

4 Make appropriate changes to the configuration. For example, you must
modify the SystemList attribute to reflect the systems in the secondary
cluster.
Make sure that the name of the service group (appgroup) is identical in both
clusters.
VVR best practice is to use the same disk group and RVG name on both
sites.
If the volume names are the same on both sides, the Mount resources will
mount the same block devices, and the same Oracle instance will start at the
secondary in case of a failover.

Linking clusters

After the VCS and VVR infrastructure has been set up at both sites, you must
link the two clusters. The Remote Cluster Configuration wizard provides an easy
interface to link clusters.

To link clusters

1 Verify that the virtual IP address for the ClusterAddress attribute for each
cluster is set.
Use the same IP address as the one assigned to the IP resource in the
ClusterService group.

2 If you are adding a cluster to an existing global cluster environment, run the
wizard from a cluster in the global cluster environment. Otherwise, run the
wizard from any cluster. From Cluster Explorer, click Edit>Add/Delete
Remote Cluster.
See “Adding a remote cluster” on page 623.

To configure an additional heartbeat between the clusters (optional)

1 On Cluster Explorer’s Edit menu, click Configure Heartbeats.

2 In the Heartbeat configuration dialog box, enter the name of the heartbeat
and select the check box next to the name of the cluster.

3 Click the icon in the Configure column to open the Heartbeat Settings dialog
box.

4 Specify the value of the Arguments attribute and various timeout and
interval fields. Click + to add an argument value; click - to delete it.
If you specify IP addresses in the Arguments attribute, make sure the IP addresses have DNS entries.

5 Click **OK**.

6 Click **OK** in the Heartbeat configuration dialog box. Now, you can monitor the state of both clusters from the Java Console:
Configuring the Steward process (optional)

In case of a two-cluster GCO, you can configure a Steward to prevent potential split-brain conditions, provided the proper network infrastructure exists.

To configure the Steward process for clusters not running in secure mode

1. Identify a system that will host the Steward process.
   Make sure both clusters can connect to the system through a ping command.

2. Copy the file steward from a node in the cluster to the Steward system. The file resides at the following path:
   \%VCS_HOME\%\bin\steward.exe
   The variable \%VCS_HOME\% represents the VCS installation directory, typically C:\Program Files\VERITAS\Cluster Server.

3. In both clusters, set the Stewards attribute to the IP address of the system running the Steward process. For example:
   cluster cluster1938 {
     UserNames = { admin = gNOgNIN\KOjOom\NOiNL }
     ClusterAddress = "10.182.147.19"
     Administrators = { admin }
     CredRenewFrequency = 0
     CounterInterval = 5
     Stewards = {"10.212.100.165"}
   }

4. On the system designated to host the Steward, start the Steward process:
   \steward.exe -start

To configure the Steward process for clusters running in secure mode

1. Verify the prerequisites for securing Steward communication are met.
   See “Prerequisites for clusters running in secure mode” on page 580.

2. Identify a system that will host the Steward process.
   Make sure both clusters can connect to the system through a ping command.

3. Copy the steward file from a node in the cluster to the Steward system. The file resides at the following path:
   \%VCS_HOME\%\bin\steward.exe
   The variable \%VCS_HOME\% represents the VCS installation directory, typically C:\\Program Files\\VERITAS\\Cluster Server.
4 Install the Symantec Product Authentication Services client on the system that is designated to run the Steward process. See the Quick Start Guide for Symantec Product Authentication Service for instructions.

5 Create an account for the Steward in any authentication broker of the clusters that are part of the global cluster. All cluster nodes serve as authentication brokers when the cluster runs in secure mode. When creating the account, make sure the following conditions are met:
   - The account name must be of the form: Steward_GCO_systemname
   - The account type must be service and the domain type must be VX.

6 Note the password used to create the account.

7 Retrieve the broker hash for the account.
   vssat showbrokerhash

8 Create a credential package (steward.cred) for this account. Note that the credential package will be bound to a system.
   vssat createpkg --prplname Steward_GCO_systemname --domain vx:HA_SERVICES@<fully_qualified_name_of_cluster_node_on_which_this_command_is_being_run> --broker systemname:2821 --password password --hash <brokerhash_obtained_in_above_step> --out steward.cred --host_ctx systemname_on_which_steward_will_run

9 Copy the file steward.cred to the system designated to run the Steward process. Copy the file to the C:\temp directory.

10 Execute the credential package on the system designated to run the Steward process.
   vssat execpkg --in <path_to_credential>\steward.cred --ob --host_ctx
   The variable <path_to_credential> represents the directory to which you copied the steward credentials.

11 On the Steward system, create a file called Steward.conf and populate it with the following information:
   broker=system_name
   accountname=accountname
   domain=HA_SERVICES@FQDN_of_system_that_issued_the_certificate

12 In both clusters, set the Stewards attribute to the IP address of the system that runs the Steward process. For example:
   cluster cluster1938 {
     UserNames = { admin = gOgNInKOjO0mWdInL }
     ClusterAddress = "10.182.147.19"
     Administrators = { admin }
CredRenewFrequency = 0
CounterInterval = 5

Stewards = {"10.212.100.165"}

On the system designated to run the Steward, start the Steward process:

```
steward.exe -start -secure
```

To stop the Steward process

When you start the Steward, the process does not release the command window. Stop the Steward process, by typing control+C in the command window or open another command window and run the command to stop the Steward process.

- To stop the Steward process that is not configured in secure mode, open a new command window and run the following command:

```
steward.exe -stop
```

- To stop the Steward process running in secure mode, open a new command window and run the following command:

```
steward.exe -stop -secure
```
Configuring the global service group

Configure the Oracle service group, appgroup, as a global group by running the Global Group Configuration wizard.

To create the global service group

1. In the service group tree of Cluster Explorer, right-click the application service group (appgroup).
2. Select **Configure As Global** from the menu.
3. Enter the details of the service group to modify (appgroup).
4. From the **Available Clusters** box, click the clusters on which the group can come online. The local cluster is not listed as it is implicitly defined to be part of the ClusterList. Click the right arrow to move the cluster name to the **ClusterList** box.
5. Select the policy for cluster failover:
   
   - **Manual** prevents a group from automatically failing over to another cluster.
   - **Auto** enables a group to automatically fail over to another cluster if it is unable to fail over within the cluster, or if the entire cluster faults.
   - **Connected** enables a group to automatically fail over to another cluster if it is unable to fail over within the cluster.

6. Click **Next**.
7. Enter or review the connection details for each cluster. Click the **Configure** icon to review the remote cluster information for each cluster.
8. Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
9. Enter the user name and the password for the remote cluster and click **OK**.
10. Click **Next**.
11. Click **Finish**.
12. Save the configuration.

The appgroup service group is now a global group and can be failed over between clusters.

For remote cluster operations, you must configure a VCS user with the same name and privileges in each cluster.

See “**User privileges in global clusters**” on page 71.
When a cluster faults

In the global cluster setup, consider a case where the primary cluster suffers a failure. The Oracle service group cannot fail over in the local cluster and must fail over globally, to a node in another cluster.

In this situation, VCS sends an alert indicating that the cluster is down. An administrator can bring the group online in the remote cluster. The RVGPrimary agent ensures that VVR volumes are made writable and the DNS agent ensures that name services are resolved to the remote site. The application can be started at the remote site.

Declaring the type of failure

If a disaster disables all processing power in your primary data center, heartbeats from the failover site to the primary data center fail. VCS sends an alert signalling cluster failure. If you choose to take action on this failure, VCS prompts you to declare the type of failure.

You can choose one of the following options to declare the failure:

- **Disaster**, implying permanent loss of the primary data center
- **Outage**, implying the primary may return to its current form in some time
- **Disconnect**, implying a split-brain condition; both clusters are up, but the link between them is broken
- **Replica**, implying that data on the takeover target has been made consistent from a backup source and that the RVGPrimary can initiate a takeover when the service group is brought online. This option applies to VVR environments only.

You can select the groups to be failed over to the local cluster, in which case VCS brings the selected groups online on a node based on the group's FailOverPolicy attribute. It also marks the groups as being offline in the other cluster. If you do not select any service groups to fail over, VCS takes no action except implicitly marking the service groups as offline in the failed cluster.

Switching the service group back to the primary

You can switch the service group back to the primary after resolving the fault at the primary site. Before switching the application to the primary site, you must resynchronize any changed data from the active Secondary site since the failover. This can be done manually through VVR or by running a VCS action from the RVGPrimary resource.
To switch the service group when the primary site has failed and the secondary did a takeover

1. In the **Service Groups** tab of the configuration tree, right-click the resource.
2. Click **Actions**.
3. Specify the details of the action:
   - From the **Action** list, choose fbsync.
   - Click the system on which to execute the action.
   - Click **OK**.
   
   This begins a fast-failback of the replicated data set. You can monitor the value of the ResourceInfo attribute for the RVG resource to determine when the resynchronization has completed.

4. Once the resynchronization completes, switch the service group to the primary cluster.
   - In the **Service Groups** tab of the Cluster Explorer configuration tree, right-click the service group.
   - Click **Switch To**, and click **Remote switch**.
   - In the Switch global group dialog box, click the cluster to switch the group. Click the specific system, or click **Any System**, and click **OK**.
Setting up a fire drill

The Disaster Recovery Fire Drill procedure tests the fault-readiness of a configuration by mimicking a failover from the primary site to the secondary site. This procedure is done without stopping the application at the primary site and disrupting user access, interrupting the flow of replicated data, or causing the secondary to need resynchronization.

The initial steps to create a fire drill service group on the secondary site that closely follows the configuration of the original application service group and contains a point-in-time copy of the production data in the Replicated Volume Group (RVG). Bringing the fire drill service group online on the secondary site demonstrates the ability of the application service group to fail over and come online at the secondary site, should the need arise. Fire drill service groups do not interact with outside clients or with other instances of resources, so they can safely come online even when the application service group is online.

You must conduct a fire drill only at the Secondary site; do not bring the fire drill service group online on the node hosting the original application.

Set an offline local dependency between the fire drill service group and the application service group to make sure a fire drill does not block an application failover in case a disaster strikes the primary site.

VCS also supports HA fire drills to verify a resource can fail over to another node in the cluster.

For detailed instructions on how to set up a fire drill in using the Solutions Configurations Center, see the following documents:

- Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide for Microsoft SQL
- Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide for Microsoft Exchange
- Veritas Storage Foundation and High Availability Solutions, Solutions Guide

Creating and configuring the fire drill service group manually

You can create the fire drill service group using the command line or Cluster Manager (Java Console.) The fire drill service group uses the duplicated copy of the application data.

Creating and configuring the fire drill service group involves the following tasks:

- “Creating the fire drill service group” on page 595
- “Linking the fire drill and replication service groups” on page 595
“Adding resources to the fire drill service group” on page 597
“Configuring the fire drill service group” on page 597
“Enabling the FireDrill attribute” on page 597

Creating the fire drill service group
This section describes how to use the Cluster Manager (Java Console) to create the fire drill service group and change the failover attribute to false so that the fire drill service group does not failover to another node during a test.

To create the fire drill service group
1. Open the Veritas Cluster Manager (Java Console). (Start>All Programs>Symantec>Veritas Cluster Manager - Java Console)
2. Log on to the cluster and click OK.
3. Click the Service Group tab in the left pane and click the Resources tab in the right pane.
4. Right-click the cluster in the left pane and click Add Service Group.
5. In the Add Service Group dialog box, provide information about the new service group.
   - In Service Group name, enter a name for the fire drill service group
   - Select systems from the Available Systems box and click the arrows to add them to the Systems for Service Group box.
   - Click OK.

To disable the AutoFailOver attribute
1. Click the Service Group tab in the left pane and select the fire drill service group.
2. Click the Properties tab in the right pane.
3. Click the Show all attributes button.
4. Double-click the AutoFailOver attribute.
5. In the Edit Attribute dialog box, clear the AutoFailOver check box.
6. Click OK to close the Edit Attribute dialog box.
7. Click the Save and Close Configuration icon in the tool bar.

Linking the fire drill and replication service groups
Create an online local firm dependency link between the fire drill service group and the replication service group.
To link the service groups

1. In Cluster Explorer, click the System tab in the left pane and click the Service Groups tab in the right pane.
2. Click Link.
3. Click the fire drill service group, drag the link and click the replication service group.
4. Define the dependency. Choose the online local and firm options and click OK.
Adding resources to the fire drill service group
Add resources to the new fire drill service group to recreate key aspects of the application service group.

To add resources to the service group
1. In Cluster Explorer, click the Service Group tab in the left pane, click the application service group and click the Resources tab in the right pane.
2. Right-click the resource at the top of the tree, select Copy and click Self and Child Nodes.
3. In the left pane, click the fire drill service group.
4. Right-click the right pane, and click Paste.
5. In the Name Clashes dialog box, specify a way for the resource names to be modified, for example, insert an FD_ prefix. Click Apply.
6. Click OK.

Configuring the fire drill service group
After copying resources to the fire drill service group, edit the resources so they will work properly with the duplicated data. The attributes must be modified to reflect the configuration at the remote site. Bringing the service group online without modifying resource attributes is likely to result in a cluster fault and interruption in service.

To configure the service group
1. In Cluster Explorer, click the Service Group tab in the left pane, click the fire drill service group in the left pane and click the Resources tab in the right pane.
2. Right-click the RVGPrimary resource and click Delete.
3. Right-click the resource to be edited and click View>Properties View. If a resource to be edited does not appear in the pane, click Show All Attributes.
4. Edit attributes to reflect the configuration at the remote site. For example, change the MountV resources so that they point to the volumes used in the fire drill service group. Similarly, reconfigure the Lanman and IP resources.

Enabling the FireDrill attribute
You must edit certain resource types so they are FireDrill-enabled. Making a resource type FireDrill-enabled changes the way that VCS checks for concurrency violations. Typically, when FireDrill is not enabled, resources can not come online on more than one node in a cluster at a time. This behavior
Setting up a fire drill prevents multiple nodes from using a single resource or from answering client requests. Fire drill service groups do not interact with outside clients or with other instances of resources, so they can safely come online even when the application service group is online.

Typically, you would enable the FireDrill attribute for the resource type used to configure the agent. For example, in a service group monitoring SQL Server, enable the FireDrill attribute for the SQLServer2000 and the MSSearch resource types.

To enable the FireDrill attribute

1. In Cluster Explorer, click the Types tab in the left pane, right-click the type to be edited, and click View > Properties View.
2. Click Show All Attributes.
3. Double click FireDrill.
4. In the Edit Attribute dialog box, enable FireDrill as required, and click OK. Repeat the process of enabling the FireDrill attribute for all required resource types.

Running the fire drill setup wizard
Multi-tiered application support using the RemoteGroup agent in a global environment

Figure 16-2 represents a two-site, two-tier environment. The application cluster, which is globally clustered between two sites, has cluster dependencies up and down the tiers. Cluster 1 (C1), depends on the remote service group for cluster 3 (C3). At the same time, cluster 2 (C2) also depends on the remote service group for cluster 4 (C4).

Figure 16-2   A VCS two-tiered globally clustered application and database

Just as a two-tier, two-site environment is possible, you can also tie a three-tier environment together.
Figure 16-3 represents a two-site, three-tier environment. The application cluster is globally clustered between two sites. The cluster has cluster dependencies up and down the tiers. Cluster 1 (C1), depends on the RemoteGroup resource on the DB tier for cluster 3 (C3), and then on the remote service group for cluster 5 (C5). The stack for C2, C4, and C6 functions the same.

**Figure 16-3** A three-tiered globally clustered application, database, and storage
Test scenario for a multi-tiered environment

In the following scenario, eight systems reside in four clusters. Each tier contains a global cluster. The global local service group in the top tier depends on the global remote service group in the bottom tier.

The following main.cf files show this multi-tiered environment. The FileOnOff resource is used to test the dependencies between layers. Note that some attributes have been edited for clarity, and that these clusters are not running in secure mode.

Figure 16-4 shows the scenario for testing.

Figure 16-4  A VCS two-tiered globally clustered scenario
The main.cf file for cluster 1

The contents of the main.cf file for cluster 1 (C1) in the top tier, containing the sysA and sysB nodes.

```plaintext
include "types.cf"

cluster C1
    ClusterAddress = "10.182.10.145"
)

remotecluster C2
    ClusterAddress = "10.182.10.146"
)

heartbeat Icmp
    ClusterList = { C2 }
    AYATimeout = 30
    Arguments @C2 = { "10.182.10.146" }
)

system sysA
)

system sysB
)

group LSG
    SystemList = { sysA = 0, sysB = 1 }
    ClusterList = { C2 = 0, C1 = 1 }
    AutoStartList = { sysA, sysB }
    ClusterFailOverPolicy = Auto
)

FileOnOff filec1
    PathName = "/tmp/c1"
)

RemoteGroup RGR
    IpAddress = "10.182.6.152"
    // The above IPAddress is the highly available address of C3—
    // the same address that the wac uses
    Username = root
    Password = xxxxyyy
    GroupName = RSG
    VCSSysName = ANY
    ControlMode = OnOff
)
The main.cf file for cluster 2

The contents of the main.cf file for cluster 2 (C2) in the top tier, containing the sysC and sysD nodes.

```plaintext
include "types.cf"

cluster C2 {
    ClusterAddress = "10.182.10.146"
}

remotecluster C1 {
    ClusterAddress = "10.182.10.145"
}

heartbeat Icmp {
    ClusterList = { C1 }
    AYATimeout = 30
    Arguments @C1 = { "10.182.10.145" }
}

system sysC {
}

system sysD {
}

group LSG {
    SystemList = { sysC = 0, sysD = 1 }
    ClusterList = { C2 = 0, C1 = 1 }
    Authority = 1
    AutoStartList = { sysC, sysD }
    ClusterFailOverPolicy = Auto
}

FileOnOff filec2 {
    PathName = filec2
}

RemoteGroup RGR {
    IpAddress = "10.182.6.154"
    // The above IPAddress is the highly available address of C4—
    // the same address that the wac uses
    Username = root
    Password = vvyyy
    GroupName = RSG
    VCSSysName = ANY
    ControlMode = OnOff
}
The main.cf file for cluster 3

The contents of the main.cf file for cluster 3 (C3) in the bottom tier, containing the sysW and sysX nodes.

include "types.cf"

cluster C3 {
    ClusterAddress = "10.182.6.152"
    remotecluster C4 {
        ClusterAddress = "10.182.6.154"
    }
    heartbeat Icmp {
        ClusterList = { C4 }
        AYATimeout = 30
        Arguments @C4 = { "10.182.6.154" }
    }
    system sysW {
        }
    system sysX {
        }
    group RSG {
        SystemList = { sysW = 0, sysX = 1 }
        ClusterList = { C3 = 1, C4 = 0 }
        AutoStartList = { sysW, sysX }
        ClusterFailOverPolicy = Auto
    }
    FileOnOff filec3 {
        PathName = "\!/tmp/filec3"
    }
}

The main.cf file for cluster 4

The contents of the main.cf file for cluster 4 (C4) in the bottom tier, containing the sysY and sysZ nodes.

include "types.cf"

cluster C4 {
    ClusterAddress = "10.182.6.154"
    remotecluster C3 {
        ClusterAddress = "10.182.6.152"
    }
}
heartbeat Icmp {
    ClusterList = { C3 }
    AYATimeout = 30
    Arguments @C3 = { "10.182.6.152" }
}

system sysY {
}

system sysZ {
}

group RSG {
    SystemList = { sysY = 0, sysZ = 1 }
    ClusterList = { C3 = 1, C4 = 0 }
    Authority = 1
    AutoStartList = { sysY, sysZ }
    ClusterFailOverPolicy = Auto
}

FileOnOff filec4 {
    PathName = "/tmp/filec4"
}
Connecting clusters—Creating global clusters

Test scenario for a multi-tiered environment
Administering global clusters from the Cluster Management Console

- About creating global service groups
- Administering global clusters
- Administering global service groups
- Administering global heartbeats
About creating global service groups

The process of creating a global cluster environment involves:

- Creating a common service group on specified local clusters and on clusters at a remote location
- Making sure the common service group is capable of being brought online on the local and remote clusters
- Designating the remote clusters as failover targets for the common service group (adding remote clusters)
- Converting the service group that is common to all the clusters to a global service group (creating the global service group)

After you set up the global cluster environment, you can configure global cluster heartbeats to monitor the health of the failover target clusters. Use the Cluster Management Console to create global service groups, to add and delete remote clusters, and to create and monitor cluster heartbeats.

See “How VCS global clusters work” on page 572.
Administering global clusters

Creating a global cluster environment requires the following conditions:

- The ClusterService group for all clusters must be properly configured for GCO operations. The resources for the NIC, IP address, and the wac process must be able to come online.
- The service group intended to serve as the global group has the same unique name on all clusters that participate in the global environment.
- The clusters all have different, unique names.
- The clusters must use the same version of VCS.
- The clusters must use the same operating system.
- The clusters are standalone and do not already belong to a global cluster environment.
- All clusters must either be configured in secure mode or not configured in secure mode. Mixing of modes is not supported.

For remote cluster operations, you must configure a VCS user with the same name and privileges in each cluster. See “User privileges in global clusters” on page 71.

Use the Cluster:Summary, Cluster:Resources, or Group:Summary views to administer a global cluster.

To navigate to the Cluster:Summary view

1. On the main tab bar, click Manage.
2. On the secondary tab bar, click Summary.
3. In the Cluster:Summary view, choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

To navigate to the Cluster:Resources view

1. On the main tab bar, click Manage.
2. On the secondary tab bar, click Resources.
3. In the Cluster:Resources view, choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.
To navigate to the Group:Summary view
1. On the main tab bar, click Manage.
2. On the secondary tab bar, click Groups.
3. In the Cluster:Groups view, in the Groups Listing table, click a linked service group name.
4. In the Group:Summary view, choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

Adding a remote cluster

Use this procedure to create global clusters by linking standalone clusters.

- If you are creating a global cluster environment for the first time with two standalone clusters, run the operation from either of the clusters.
- If you are adding a standalone cluster to an existing global cluster environment, run the operation from a cluster already in the global cluster environment.

The following information is required for this procedure:

- The IP address of the cluster, the IP address of a system in the cluster, or the name of a system in the cluster being added to the configuration.
- The user name and password of the administrator for the cluster being added to the configuration.

Symantec does not support adding a cluster that is already part of a global cluster environment. To merge the clusters of one global cluster environment (for example, cluster A and cluster B) with the clusters of another global environment (for example, cluster C and cluster D), separate cluster C and cluster D into standalone clusters and add them one by one to the environment containing cluster A and cluster B.

To add a remote cluster to a global environment

1. In the Cluster:Summary view, in the Configuration task panel, click Add/ Delete Remote Cluster.
2. In the Remote Cluster Configuration wizard, read the introductory information and then click Next.
3. In the Configuration Options dialog box, click Add Cluster and then click Next.
4. Do one of the following:
   - For clusters not running in secure mode
In the **Connection Details** dialog box, specify the following details for the connection to the remote cluster and then click **Next**:

- **A name or address**
  Enter the IP address of the cluster, the IP address of a cluster system, or the name of a cluster system.

- **The port**
  Verify the port number. The default is 14141.

- **An administrator user name and password.**
  Enter an administrator-level user name and password that is valid on the remote cluster.

- **For clusters running in secure mode**
  In the **Connection Details** dialog box, specify the following details for the connection to the remote cluster and then click **Next**:

  - **A name or address**
    Enter the IP address of the cluster, the IP address of a cluster system, or the name of a cluster system.

  - **The port**
    Verify the port number. The default is 14141.

  - **Authentication credentials**
    Choose to connect to the remote cluster with the credentials used for the current cluster connection or enter new credentials. You must specify the user name, password, domain, and domain type. If you have connected to the remote cluster before using this wizard, you can use the credentials from the previous connection.

5. Click **Finish**.

The cluster icon changes to indicate that the cluster is a global cluster.

**Deleting a remote cluster**

This operation involves the following tasks:

- **Taking the Process resource configured to monitor the wac process offline in the cluster to be removed from the global environment.** For example, to delete cluster C2 from a global environment containing C1 and C2, log in to C2 and take the wac resource offline.

- **Removing the name of the specified cluster (C2) from the cluster lists of all global groups.** The Cluster Management Console updates the cluster lists for heartbeats. Log in to the local cluster (C1) to complete this task using the Global Groups Wizard.
Removing the cluster (C2) from the local cluster (C1) using the Cluster:Summary view on the local cluster (C1).

**Note:** You cannot delete a remote cluster if the cluster is part of a cluster list for global service groups or global heartbeats, or if the cluster is in the RUNNING, BUILD, INQUIRY, EXITING, or TRANSITIONING states.

---

**To take the wac resource offline**

1. In the **Cluster:Resources** view, in the **Resources Listing** table, click the linked name of the **wac** resource. The resource is configured as a resource of type Process.

2. In the **Resource:Summary** view, in the **Operations** task panel, click **Offline**.

3. In the **Offline Resource** dialog box, select the system on which you want to take the **wac** resource offline from the drop-down menu.

4. Click **OK**.

**To remove a cluster from the cluster list for a global group**

1. In the **Group:Summary** view, in the **Configuration** task panel, click **Configure Global Group**.

2. In the **Global Group Configuration** wizard, read the introductory information and then click **Next**.

3. In the **Cluster List Configuration** dialog box, under **Selected Clusters**, click the name of the cluster that you want to remove. Click the << (left-arrow) button.
   
   This action removes the cluster from the cluster list for the selected global service group and places it back under **Available Clusters**. To remove all clusters, click the << (double-left-arrow) button.

4. Select the failover policy for the global service group and then click **Next**:
   - **Manual** prevents the service group from automatically failing over to another cluster.
   - **Auto** enables the service group to automatically fail over to another cluster if it is unable to fail over within the cluster, or if the entire cluster faults.
   - **Connected** enables the service group to automatically fail over to another cluster if it is unable to fail over within the cluster.

5. In this step, you update the cluster list of remaining instances of the selected global service group. To perform the update, you must first verify or supply the authentication credentials for each remaining global cluster in
the list. The Cluster Management Console can then connect to those clusters and update the lists.

In the **Remote Cluster Configuration** dialog box, verify the required information for the remaining remote clusters and then click **Next**. To change authentication information, click a cluster name under **Existing Clusters** and then enter the authentication information in the fields to the right. The requisite information in this dialog box varies depending upon whether or not the cluster is secure (uses an authentication broker).

6  Click **Next**.

7  Click **Finish**.

You must repeat this procedure for all global service groups that are configured on the global cluster to be removed.

To remove a remote cluster from the local cluster

1  In the **Cluster:Summary** view, in the **Configuration** task panel, click **Add/Delete Remote Cluster**.

2  In the **Remote Cluster Configuration** wizard, select the cluster to delete and then click **Next**.

   The cluster that you want to delete cannot be in a running state.

3  In this step, you update the global cluster list of available global clusters. To perform the update, you must first verify or supply the authentication credentials for each remaining global cluster. The Cluster Management Console can then connect to those clusters and update the list.

   In the **Remote Cluster Configuration** dialog box, verify the required information for the remaining remote clusters and then click **Next**. To change authentication information, click a cluster name under **Existing Clusters** and then enter the authentication information in the fields to the right. The requisite information in this dialog box varies depending upon whether or not the cluster is secure (uses an authentication broker).

4  Click **Next**.

5  Click **Finish**.
Administering global service groups

After connecting clusters in a global cluster environment, use the Global Group Configuration wizard to convert a local service group that is common to the global clusters to a global group. This wizard also enables you to convert global groups into local groups.

Administering global groups requires the following conditions:

- A group that is intended to serve as the global group must have the same name across all applicable clusters.
- You must know the user name and password for the administrator for each cluster in the configuration.

Use the Cluster:Summary, Cluster:Resources, or Group:Summary views to administer a global service group.

**To navigate to the Cluster:Summary view**
1. On the main tab bar, click **Manage**.
2. On the secondary tab bar, click **Summary**.
3. In the **Cluster:Summary** view, choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

**To navigate to the Cluster:Resources view**
1. On the main tab bar, click **Manage**.
2. On the secondary tab bar, click **Summary** and then click **Resources**.
3. In the **Cluster:Resources** view, choose a task from the task pane or select another cluster-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the cluster.

**To navigate to the Group:Summary view**
1. On the main tab bar, click **Manage**.
2. On the secondary tab bar, click **Groups**.
3. In the **Cluster:Groups** view, in the **Groups Listing** table, click a linked service group name.
4. In the **Group:Summary** view, choose a task from the task pane or select another service-group-level view using the tabs on the secondary tab bar. Each view contains information and tasks for administering the service group.
Converting local service groups to global service groups

Use the Global Group Configuration wizard to configure a service group in a local cluster as a global service group.

To convert a service group on a local cluster to a global service group

1. In the Cluster:Summary view, in the Groups Listing table, click the linked name of the service group that you want to convert. This service group should already have been configured on at least one local and one remote cluster.

2. In the Group:Summary view, in the Configuration task panel, click Configure Global Group.

3. In the Global Group Configuration wizard, read the introductory information and click Next.

4. In the Cluster List Configuration dialog box, under Available Clusters, select the clusters on which the global service group can come online. To select a cluster, click the right-arrow button to move the cluster name under Selected Clusters.

5. Select the policy for service group failover and then click Next:
   - Manual prevents a service group from automatically failing over to another cluster.
   - Auto enables a service group to automatically fail over to another cluster if it is unable to fail over within the cluster, or if the entire cluster faults.
   - Connected enables a service group to automatically fail over to another cluster if it is unable to fail over within the cluster.

6. Update the cluster list of remaining instances of the selected global service group. To perform the update, you must first verify or supply the authentication credentials for each remaining global cluster in the list. In the Remote Cluster Configuration dialog box, verify the required information for the remaining remote clusters and then click Next. To change authentication information, click a cluster name under Existing Clusters and then enter the authentication information in the fields to the right. The requisite information in this dialog box varies depending upon whether or not the cluster is secure (uses an authentication broker).

7. Click No if you want the operation to be completed only if the wizard can connect to all selected clusters.

8. Click Next.

9. Click Finish.
Administering global clusters from the Cluster Management Console

Administering global service groups

Bringing a remote service group online

Manually put a remote service group into a responsive, functioning state. You must have the role of cluster administrator or service group administrator to bring a remote service group online.

You can bring a remote service group online on a specific system, or you can bring the service group online “anywhere” in the remote cluster. If you select the Anywhere option, the service group is brought online on the first available system in the remote cluster.

To bring a remote service group online

1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the offline service group that you want to bring online.
2. In the Group:Summary view, in the Remote Operations task panel, click Online.
3. In the Online Service Group dialog box, specify the following details for the task and then click OK:
   - The target cluster
     Select the cluster on which you want to bring the remote service group online from the Select the cluster you want to online this group on drop-down menu. The cluster choices are populated using the cluster list for the remote service group.
   - The target system
     Select the system on which you want to bring the remote service group online from the Select the system you want to online this group on drop-down menu. The system choices are populated using the system list for the remote service group. The Anywhere option causes this task to try each system in the list until the service group is successfully brought online.

Taking a remote service group offline

Manually put a remote service group into an unresponsive, nonfunctioning state. You must have the role of cluster administrator or service group administrator to take a service group offline.

You can take a remote service group offline on a specific system, or you can take the service group offline “anywhere”. If you select the Anywhere option, the service group is taken offline on the first system in the remote cluster on which it is found.
To take a remote service group offline

1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the online service group that you want to take offline.

2. In the Group:Summary view, in the Remote Operations task panel, click Offline.

3. In the Offline Service Group dialog box, specify the following details for the task and then click OK:
   - The target cluster
     Select the cluster on which you want to take the remote service group offline from the Select the cluster you want to offline this group on drop-down menu. The cluster choices are populated using the cluster list for the remote service group.
   - The target system
     Select the system on which you want to take the remote service group offline from the Select the system you want to offline this group on drop-down menu.
     The system choices are populated using the system list for the remote service group. The Anywhere option causes this task to take the service group offline on the first system it is found to be running.

Switching a remote service group

Take a service group offline on one system in a cluster and bring it online on another system using a single task.

To switch a service group to another system

1. In the Cluster:Groups view, in the Groups Listing table, click the linked name of the remote service group that you want to switch.

2. In the Group:Summary view, in the Remote Operations task panel, click Switch.

3. In the Switch Service Group dialog box, specify the following details for the task and then click OK:
   - The target cluster
     Select the cluster to which you want to switch the remote service group from the Select the cluster you want to switch this group to drop-down menu. The cluster choices are populated using the cluster list for the remote service group.
   - The target system
Administering global heartbeats

Select the system to which you want to switch the remote service group from the **Select the system you want to online this group on** drop-down menu.

The system choices are populated using the system list for the remote service group. The **Anywhere** option causes this task to try every other system in the list until the service group is successfully brought online.

**Administering global heartbeats**

Use cluster heartbeats to monitor the health of clusters configured into a global cluster environment. A heartbeat is a list of clusters to which the Cluster Management Console listens. The console listens for repetitive signals that confirm that communications with each cluster are valid and that each cluster is in an online state. Global clustering requires a minimum of one heartbeat between clusters; you can add additional heartbeats as a precautionary measure.

Use the Cluster:Heartbeats view to manage heartbeats. The Cluster Heartbeats tab is available only if global service groups are configured.

**To navigate to the Cluster:Heartbeats view**

1. On the main tab bar, click **Management**.
2. On the secondary tab bar, click **Cluster Heartbeats**.
Adding a global heartbeat

Add a heartbeat to monitor the health of a remote cluster that is configured in a global cluster environment.

**To add a global heartbeat**

1. In the Cluster:Heartbeats view, in the Configuration task panel, click **Add Heartbeat**.

2. In the **Add Heartbeat** dialog box, specify the following details for the heartbeat and then click **OK**:
   - The heartbeat name
     Enter a name for the heartbeat that is indicative of the generating it.
   - The global clusters to add to the cluster list for the heartbeat.
     In the **Cluster List for Heartbeat** table, check the box preceding the line item for each cluster that you want to participate in the heartbeat. Clear the check box to exclude clusters from the heartbeat list.
   - The Arguments attribute value, interval, and timeout options.
     Click the ... (edit) button in the **Settings** column to specify the value for the Arguments attribute, the timeout options, and the interval options. Click **Save** to exit these options and save your selections.

Deleting a global heartbeat

Delete a heartbeat that is monitoring the health of a remote cluster that is configured in a global cluster environment.

**Note:** You cannot delete the heartbeat if it is the only remaining heartbeat between a global and remote cluster.

**To delete a global heartbeat**

1. In the Cluster:Heartbeats view, in the **Heartbeats Listing** table, click the X button in the line item corresponding to the heartbeat that you want to delete.

2. Click **OK** to confirm that you want to delete the heartbeat.
Modifying a global heartbeat

Change the clusters that participate in a heartbeat and the heartbeat parameters at any time.

1. In the Cluster:Heartbeats view, in the Heartbeats Listing table, click the ... (edit) button in the line item corresponding to the heartbeat that you want to modify.

2. In the Edit Heartbeat dialog box, specify the following details for the heartbeat and then click OK:
   - The heartbeat name
     Enter a name for the heartbeat that is indicative of the generating it.
   - The global clusters to add to the cluster list for the heartbeat.
     In the Cluster List for Heartbeat table, check the box preceding the line item for each cluster that you want to participate in the heartbeat. Clear the check box to exclude clusters from the heartbeat list.
   - The Arguments attribute value, interval, and timeout options.
     Click the ... (edit) button in the Settings column to specify the value for the Arguments attribute, the timeout options, and the interval options. Click Save to exit these options and save your isolations.
Administering global clusters from Cluster Manager (Java console)

- About global clusters
- Adding a remote cluster
- Deleting a remote cluster
- Administering global service groups
- Administering global heartbeats
About global clusters

The process of creating a global cluster environment involves creating a common service group for specified clusters, making sure all the service groups are capable of being brought online in the specified clusters, connecting the standalone clusters, and converting the service group that is common to all the clusters to a global service group. Use the console to add and delete remote clusters, create global service groups, and manage cluster heartbeats.

Creating a global cluster environment requires the following conditions:

- All service groups are properly configured and able to come online.
- The service group that will serve as the global group has the same unique name across all applicable clusters.
- The clusters must use the same version of VCS.
- The clusters must use the same operating system.
- The clusters are standalone and do not already belong to a global cluster environment.

Through the Java Console, you can simulate the process of generating and clearing global cluster faults in an OFFLINE state. Use VCS Simulator to complete these operations.

See “Predicting VCS behavior using VCS Simulator” on page 457.

For remote cluster operations, you must configure a VCS user with the same name and privileges in each cluster.

See “User privileges in global clusters” on page 71.
Adding a remote cluster

Cluster Explorer provides a wizard to create global clusters by linking standalone clusters. Command Center only enables you to perform remote cluster operations on the local cluster.

- If you are creating a global cluster environment for the first time with two standalone clusters, run the wizard from either of the clusters.
- If you are adding a standalone cluster to an existing global cluster environment, run the wizard from a cluster already in the global cluster environment.

The following information is required for the Remote Cluster Configuration Wizard in Cluster Explorer:

- The active host name or IP address of each cluster in the global configuration and of the cluster being added to the configuration.
- The user name and password of the administrator for each cluster in the configuration.
- The user name and password of the administrator for the cluster being added to the configuration.

**Note:** Symantec does not support adding a cluster that is already part of a global cluster environment. To merge the clusters of one global cluster environment (for example, cluster A and cluster B) with the clusters of another global environment (for example, cluster C and cluster D), separate cluster C and cluster D into standalone clusters and add them one by one to the environment containing cluster A and cluster B.

To add a remote cluster to a global cluster environment in Cluster Explorer

1. From Cluster Explorer, click **Add/Delete Remote Cluster** on the **Edit** menu.
   or
   From the Cluster Explorer configuration tree, right-click the cluster name, and click **Add/Delete Remote Clusters**.

2. Review the required information for the **Remote Cluster Configuration Wizard** and click **Next**.

3. In the Wizard Options dialog box:
   - Click **Add Cluster**.
   - Click **Next**.

4. Enter the details of the new cluster:
If the cluster is not running in secure mode:

- Enter the host name of a cluster system, an IP address of a cluster system, or the IP address of the cluster that will join the global environment.
- Verify the port number.
- Enter the user name and the password.
- Click Next.

If the cluster is running in secure mode:

- Enter the host name of a cluster system, an IP address of a cluster system, or the IP address of the cluster that will join the global environment.
- Verify the port number.
- Choose to connect to the remote cluster with the credentials used for the current cluster connection or enter new credentials, including the user name, password, and the domain.
  If you have connected to the remote cluster using the wizard earlier, you can use the credentials from the previous connection.
Click **Next**.

5 Enter the details of the existing remote clusters; this information on administrator rights enables the wizard to connect to all the clusters and make changes to the configuration:

![Remote cluster configuration dialog box](image)

6 Click the **Configure** icon. The Remote cluster information dialog box is displayed.

**If the cluster is not running in secure mode:**

- Enter the host name of a cluster system, an IP address of a cluster system, or the IP address of the cluster that will join the global environment.
- Verify the port number.
- Enter the user name.
- Enter the password.
- Click **OK**.
- Repeat these steps for each cluster in the global environment.
Adding a remote cluster

If the cluster is running in secure mode:

- Enter the host name of a cluster system, an IP address of a cluster system, or the IP address of the cluster that will join the global environment.
- Verify the port number.
- Choose to connect to the remote cluster with the credentials used for the current cluster connection or enter new credentials, including the user name, password, and the domain.
- Click OK.

7 Click Next.

8 Click Finish. After running the wizard, the configurations on all the relevant clusters are opened and changed; the wizard does not close the configurations.

To add a remote cluster to a global cluster environment in Command Center

Note: Command Center enables you to perform operations on the local cluster; this does not affect the overall global cluster configuration.

1 Click Commands>Configuration>Cluster Objects>Add Remote Cluster.
2 Enter the name of the cluster.
3 Enter the IP address of the cluster.
4 Click Apply.
Deleting a remote cluster

The Remote Cluster Configuration Wizard enables you to delete a remote cluster. This operation involves the following tasks:

- Taking the ApplicationProcess resource configured to monitor the wac resource offline on the cluster that will be removed from the global environment. For example, to delete cluster C2 from a global environment containing C1 and C2, log on to C2 and take the wac resource offline.

- Removing the name of the specified cluster (C2) from the cluster lists of the other global groups using the Global Group Configuration Wizard. Note that the Remote Cluster Configuration Wizard in Cluster Explorer updates the cluster lists for heartbeats. Log on to the local cluster (C1) to complete this task before using the Global Group Configuration Wizard.

- Deleting the cluster (C2) from the local cluster (C1) through the Remote Cluster Configuration Wizard.

**Note:** You cannot delete a remote cluster if the cluster is part of a cluster list for global service groups or global heartbeats, or if the cluster is in the RUNNING, BUILD, INQUIRY, EXITING, or TRANSITIONING states.

To take the wac resource offline

1. From Cluster Monitor, log on to the cluster that will be deleted from the global cluster environment.

2. In the Service Groups tab of the Cluster Explorer configuration tree, right-click the wac resource under the Process type in the ClusterService group. 
   or
   Click the ClusterService group in the configuration tree, click the Resources tab, and right-click the resource in the view panel.

3. Click Offline, and click the appropriate system from the menu.

To remove a cluster from a cluster list for a global group

1. From Cluster Explorer, click Configure Global Groups on the Edit menu.

2. Click Next.

3. Enter the details of the service group to modify:
   - Click the name of the service group.
   - For global to local cluster conversion, click the left arrow to move the cluster name from the cluster list back to the Available Clusters box.
   - Click Next.
4 Enter or review the connection details for each cluster. Click the Configure icon to review the remote cluster information for each cluster.

**If the cluster is not running in secure mode:**
- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
- Enter the user name.
- Enter the password.
- Click OK.

**If the cluster is running in secure mode:**
- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
- Choose to connect to the remote cluster using the connected cluster’s credentials or enter new credentials, including the user name, password, and the domain.
- Click OK.

5 Click Next.

6 Click Finish.

**To delete a remote cluster from the local cluster**

1 From Cluster Explorer, click Add/Delete Remote Cluster on the Edit menu.  
   or 
   From the Cluster Explorer configuration tree, right-click the cluster name, and click Add/Delete Remote Clusters.

2 Review the required information for the Remote Cluster Configuration Wizard and click Next.

3 In the Wizard Options dialog box:
   - Click Delete Cluster.
   - Click Next.

4 In the Delete Cluster dialog box:
   - Click the name of the remote cluster to delete.
   - Click Next.
5 Review the connection details for each cluster. Click the Configure icon to review the remote cluster information for each cluster.

![Remote Cluster Configuration Wizard](image)

**If the cluster is not running in secure mode:**

- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
- Enter the user name.
- Enter the password.
- Click OK.

**If the cluster is running in secure mode:**

- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
- Choose to connect to the remote cluster with the credentials used for the current cluster connection or enter new credentials, including the user name, password, and the domain.
  - If you have connected to the remote cluster using the wizard earlier, you can use the credentials from the previous connection.
- Click OK.

6 Click Finish.
Administering global service groups

After connecting clusters in a global cluster environment, use the Global Group Configuration Wizard to convert a local service group that is common to the global clusters to a global group. This wizard also enables you to convert global groups into local groups.

Administering global groups requires the following conditions:

■ A group that will serve as the global group must have the same name across all applicable clusters.
■ You must know the user name and password for the administrator for each cluster in the configuration.

Use Cluster Explorer to bring a global group online and take a global group offline on a remote cluster.

Converting local and global groups

1. From Cluster Explorer, click Configure Global Groups... on the Edit menu. or
   From the Cluster Explorer configuration tree, right-click the service group, click Configure As Global... or Make Local... and proceed to step 3b.

2. Review the information required for the Global Group Configuration Wizard and click Next.

3. Enter the details of the service group to modify:

   - Click the name of the service group that will be converted from a local group to a global group, or vice versa.
   - From the Available Clusters box, click the clusters on which the group can come online. Click the right arrow to move the cluster name to the Clusters for Service Group box; for global to local cluster conversion,
click the left arrow to move the cluster name back to the Available Clusters box. A priority number (starting with 0) indicates the cluster in which the group will attempt to come online. If necessary, double-click the entry in the Priority column to enter a new value.

Select the policy for cluster failover:

- **Manual** prevents a group from automatically failing over to another cluster.
- **Auto** enables a group to automatically fail over to another cluster if it is unable to fail over within the cluster, or if the entire cluster faults.
- **Connected** enables a group to automatically fail over to another cluster if it is unable to fail over within the cluster.

Click **Next**.

4  Enter or review the connection details for each cluster:

Click the Configure icon to review the remote cluster information for each cluster.

**If the cluster is not running in secure mode:**

- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
- Enter the user name and password.
- Click **OK**.

Repeat these steps for each cluster in the global environment.

**If the cluster is running in secure mode:**

- Enter the IP address of the remote cluster, the IP address of a cluster system, or the host name of a cluster system.
- Verify the port number.
Choose to connect to the remote cluster with the credentials used for the current cluster connection, or enter new credentials, including the user name, password, and the domain.
If you have connected to the remote cluster using the wizard earlier, you can use the credentials from the previous connection.

- Click OK.
Repeat these steps for each cluster in the global environment.

5 In the Remote cluster information dialog box, click Next.

6 Click Finish.

Bringing a service group online in a remote cluster

1 In the Service Groups tab of the Cluster Explorer configuration tree of a local cluster, right-click the service group.
   or
   Click a local cluster in the configuration tree, click the Service Groups tab, and right-click the service group icon in the view panel.

2 Click Online, and click Remote online...

3 In the Online global group dialog box:
   - Click the remote cluster to bring the group online.
   - Click the specific system, or click Any System, to bring the group online.
   - Click OK.

4 In the Question dialog box, click Yes.
Taking a service group offline in a remote cluster

1. In the **Service Groups** tab of the Cluster Explorer configuration tree of a local cluster, right-click the service group.
   or
   Click a local cluster in the configuration tree, click the **Service Groups** tab, and right-click the service group icon in the view panel.
2. Click **Offline**, and click **Remote offline**...
3. In the Offline global group dialog box:
   - Click the remote cluster to take the group offline.
   - Click the specific system, or click **All Systems**, to take the group offline.
   - Click **OK**.
4. In the Question dialog box, click **Yes**.

Switching a service group to a remote cluster

1. In the **Service Groups** tab of the Cluster Explorer configuration tree of a local cluster, right-click the service group.
   or
   Click a local cluster in the configuration tree, click the **Service Groups** tab, and right-click the service group icon in the view panel.
2. Click **Switch To**, and click **Remote switch**...
3. In the Switch global group dialog box:
   - Click the cluster to switch the group.
   - Click the specific system, or click **Any System**, to switch the group.
   - Click **OK**.
4. In the Question dialog box, click **Yes**.
Administering global heartbeats

Use Cluster Explorer to add, modify, and delete heartbeats in a global cluster environment. Icmp heartbeats send Icmp packets simultaneously to all IP addresses; IcmpS heartbeats send individual Icmp packets to IP addresses in serial order. Global clustering requires a minimum of one heartbeat between clusters; the Icmp heartbeat is added when the cluster is added to the environment. You can add additional heartbeats as a precautionary measure.

Adding a global heartbeat

To add a cluster heartbeat from Cluster Explorer

1. Click **Configure Heartbeats** on the **Edit** menu.
2. In the Heartbeat Configuration dialog box:

   - Enter the name of the heartbeat.
   - Select the check box next to the name of the cluster to add it to the cluster list for the heartbeat.
   - Click the icon in the **Configure** column to open the Heartbeat Settings dialog box.
Specify the value of the Arguments attribute and various timeout and interval fields. Click + to add an argument value; click - to delete it.

- Click OK.
- Click OK on the Heartbeat configuration dialog box.

To add a cluster heartbeat from Command Center

1. Click Commands > Configuration > Cluster Objects > Add Heartbeat.
2. Enter the name of the heartbeat.
3. Click Apply.
Modifying a global heartbeat

1. From Cluster Explorer, click **Configure Heartbeats** on the **Edit** menu.

2. In the Heartbeat Configuration dialog box:

   - Click **Existing Heartbeat**.
   - Click the name of the existing heartbeat from the menu.
   - Select or clear the check box next to the name of a cluster to add or remove it from the cluster list for the heartbeat.
   - If necessary, click the icon in the **Configure** column to open the Heartbeat Settings dialog box. Otherwise, proceed to the last step.
   - Change the values of the Arguments attribute and various timeout and interval fields. Click + to add an argument value; click - to delete it.

   ![Heartbeat Configuration dialog box](image)

   - Click **OK**.
   - Click **OK** on the Heartbeat Configuration dialog box.
Deleting a global heartbeat

You cannot delete the last heartbeat between global clusters.

To delete a cluster heartbeat from Command Center

1. Click **Commands > Configuration > Cluster Objects > Delete Heartbeat**.
2. Click the heartbeat to delete.
3. Click **Apply**.
Administering global clusters from Cluster Manager (Java console)

Administering global heartbeats
Chapter 19

Administering global clusters from the command line

- About administering global clusters from the command line
- Global querying
- Administering global service groups
- Administering resources
- Administering clusters in global clusters
- Administering heartbeats
About administering global clusters from the command line

For remote cluster operations, you must configure a VCS user with the same name and privileges in each cluster.
See “User privileges in global clusters” on page 71.

Global querying

VCS enables you to query global cluster objects, including service groups, resources, systems, resource types, agents, and clusters. You may enter query commands from any system in the cluster. Commands to display information on the global cluster configuration or system states can be executed by all users; you do not need root privileges. Only global service groups may be queried.

Querying global cluster service groups

To display service group attribute values across clusters

```
  hagrp -value service_group attribute [system] [-clus cluster | -localclus]
```

The option `-clus` displays the attribute value on the cluster designated by the variable `cluster`; the option `-localclus` specifies the local cluster.
If the attribute has local scope, you must specify the system name, except when querying the attribute on the system from which you run the command.

To display the state of a service group across clusters

```
  hagrp -state [service_groups -sys systems] [-clus cluster | -localclus]
```

The option `-clus` displays the state of all service groups on a cluster designated by the variable `cluster`; the option `-localclus` specifies the local cluster.

To display service group information across clusters

```
  hagrp -display [service_groups] [-attribute attributes] [-sys systems] [-clus cluster | -localclus]
```

The option `-clus` applies to global groups only. If the group is local, the cluster name must be the local cluster name, otherwise no information is displayed.
To display service groups in a cluster

```
hagrp -list [conditionals] [-clus cluster | -localclus]
```

The option `-clus` lists all service groups on the cluster designated by the variable `cluster`; the option `-localclus` specifies the local cluster.

To display usage for the service group command

```
hagrp [-help [-modify|-link|-list]]
```
Querying resources

To display resource attribute values across clusters

```
hares -value resource attribute [system] [-clus cluster | -localclus]
```

The option `-clus` displays the attribute value on the cluster designated by the variable `cluster`; the option `-localclus` specifies the local cluster. If the attribute has local scope, you must specify the system name, except when querying the attribute on the system from which you run the command.

To display the state of a resource across clusters

```
hares -state [resource -sys system] [-clus cluster | -localclus]
```

The option `-clus` displays the state of all resources on the specified cluster; the option `-localclus` specifies the local cluster. Specifying a system displays resource state on a particular system.

To display resource information across clusters

```
hares -display [resources] [-attribute attributes] [-group service_groups] [-type types] [-sys systems] [-clus cluster | -localclus]
```

The option `-clus` lists all service groups on the cluster designated by the variable `cluster`; the option `-localclus` specifies the local cluster.

For a list of resources across clusters

```
hares -list [conditionals] [-clus cluster | -localclus]
```

The option `-clus` lists all resources that meet the specified conditions in global service groups on a cluster as designated by the variable `cluster`.

To display usage for the resource command

```
hares -help [-modify | -list]
```
Querying systems

To display system attribute values across clusters

```
hasys -value system attribute [-clus cluster | -localclus]
```

The option -clus displays the values of a system attribute in the cluster as designated by the variable *cluster*; the option -localclus specifies the local cluster.

To display the state of a system across clusters

```
hasys -state [system] [-clus cluster | -localclus]
```

Displays the current state of the specified system. The option -clus displays the state in a cluster designated by the variable *cluster*; the option -localclus specifies the local cluster. If you do not specify a system, the command displays the states of all systems.

For information about each system across clusters

```
hasys -display [systems] [-attribute attributes] [-clus cluster | -localclus]
```

The option -clus displays the attribute values on systems (if specified) in a cluster designated by the variable *cluster*; the option -localclus specifies the local cluster.

For a list of systems across clusters

```
hasys -list [conditionals] [-clus cluster | -localclus]
```

Displays a list of systems whose values match the given conditional statements. The option -clus displays the systems in a cluster designated by the variable *cluster*; the option -localclus specifies the local cluster.
Querying clusters

For the value of a specific cluster attribute on a specific cluster

```bash
hacclus -value attribute [cluster] [-localclus]
```

The attribute must be specified in this command. If you do not specify the cluster name, the command displays the attribute value on the local cluster.

To display the state of a local or remote cluster

```bash
hacclus -state [cluster] [-localclus]
```

The variable `cluster` represents the cluster. If a cluster is not specified, the state of the local cluster and the state of all remote cluster objects as seen by the local cluster are displayed.

For information on the state of a local or remote cluster

```bash
hacclus -display [cluster] [-localclus]
```

If a cluster is not specified, information on the local cluster is displayed.

For a list of local and remote clusters

```bash
hacclus -list [conditionals]
```

Lists the clusters that meet the specified conditions, beginning with the local cluster.

To display usage for the cluster command

```bash
hacclus [-help [-modify]]
```

To display the status of a faulted cluster

```bash
hacclus -status cluster
```

Displays the status on the specified faulted cluster. If no cluster is specified, the command displays the status on all faulted clusters. It lists the service groups that were not in the OFFLINE or the FAULTED state before the fault occurred. It also suggests corrective action for the listed clusters and service groups.

Querying status

For the status of local and remote clusters

```bash
hastatus
```
Querying heartbeats

The `hahb` command is used to manage WAN heartbeats that emanate from the local cluster. Administrators can monitor the “health of the remote cluster via heartbeat commands and mechanisms such as Internet, satellites, or storage replication technologies. Heartbeat commands are applicable only on the cluster from which they are issued.

**Note:** You must have Cluster Administrator privileges to add, delete, and modify heartbeats.

The following commands are issued from the command line.

**For a list of heartbeats configured on the local cluster**

```
    hahb -list \[conditionals\]
```

The variable `conditionals` represents the conditions that must be met for the heartbeat to be listed.

**To display information on heartbeats configured in the local cluster**

```
    hahb -display \[heartbeat \...\]
```

If `heartbeat` is not specified, information regarding all heartbeats configured on the local cluster is displayed.

**To display the state of the heartbeats in remote clusters**

```
    hahb -state \[heartbeat\] \[-clus \cluster\]
```

For example, to get the state of heartbeat ICMP from the local cluster to the remote cluster phoenix:

```
    hahb -state ICMP -clus phoenix
```
To display an attribute value of a configured heartbeat

```
  hahb -value heartbeat attribute [-clus cluster]
```

The `-value` option provides the value of a single attribute for a specific heartbeat. The cluster name must be specified for cluster-specific attribute values, but not for global.

For example, to display the value of the ClusterList attribute for heartbeat ICMP:

```
  hahb -value Icmp ClusterList
```

Note that ClusterList is a global attribute.

To display usage for the command `hahb`

```
  hahb [-help [-modify]]
```

If the `-modify` option is specified, the usage for the `hahb -modify` option is displayed.
**Administering global service groups**

Operations for the VCS global clusters option are enabled or restricted depending on the permissions with which you log on. The privileges associated with each user role are enforced for cross-cluster, service group operations. See “User privileges in global clusters” on page 71.

To bring a service group online across clusters for the first time

```
hagrp -online -force
```

To bring a service group online across clusters

```
hagrp -online service_group -sys system [-clus cluster | -localclus]
```

The option `-clus` brings the service group online on the system designated in the cluster. If a system is not specified, the service group is brought online on any node within the cluster. The option `-localclus` brings the service group online in the local cluster.

To bring a service group online on any node

```
hagrp -online [-force] service_group -any [-clus cluster | -localclus]
```

The option `-any` specifies that HAD brings a failover group online on the optimal system, based on the requirements of service group workload management and existing group dependencies. If bringing a parallel group online, HAD brings the group online on each system designated in the SystemList attribute.

To take a service group offline across clusters

```
hagrp -offline [-force] [-ifprobed] service_group -sys system [-clus cluster | -localclus]
```

The option `-clus` takes offline the service group on the system designated in the cluster.

To take a service group offline anywhere

```
hagrp -offline [-ifprobed] service_group -any [-clus cluster | -localclus]
```

The option `-any` specifies that HAD takes a failover group offline on the system on which it is online. For a parallel group, HAD takes the group offline on each system on which the group is online. HAD adheres to the existing group dependencies when taking groups offline.
To switch a service group across clusters

```
hagrp -switch service_group -to system [-clus cluster | -localclus [-nopre]]
```

The option `-clus` identifies the cluster to which the service group will be switched. The service group is brought online on the system specified by the `-to system` argument. If a system is not specified, the service group may be switched to any node within the specified cluster.

The option `-nopre` indicates that the VCS engine must switch the service group regardless of the value of the PreSwitch service group attribute.

See “Service group attributes” on page 764.

To switch a service group anywhere

```
hagrp -switch service_group -any [-clus cluster | -localclus]
```

The `-any` option specifies that the VCS engine switches a service group to the best possible system on which it is currently not online, based on the value of the group’s FailOverPolicy attribute. The VCS engine switches a global service group from a system to another system in the local cluster or a remote cluster.

If you do not specify the `-clus` option, the VCS engine by default assumes `-localclus` option and selects an available system within the local cluster.

The option `-clus` identifies the remote cluster to which the service group will be switched. The VCS engine then selects the target system on which to switch the service group.

To switch a parallel global service group across clusters

```
hagrp -switch service_group -any -clus remote_cluster
```

VCS brings the parallel service group online on all possible nodes in the remote cluster.
Administering resources

To take action on a resource across clusters

```
hares -action resource token [-actionargs arg1 ...]
[-sys system] [-clus cluster | -localclus]
```

The option `-clus` implies resources on the cluster. If the designated system is not part of the local cluster, an error is displayed. If the `-sys` option is not used, it implies resources on the local node.

To invoke the Info function across clusters

```
hares -refreshinfo resource [-sys system] [-clus cluster | -localclus]
```

Causes the Info function to update the value of the ResourceInfo resource level attribute for the specified resource if the resource is online. If no system or remote cluster is specified, the Info function runs on local system(s) where the resource is online.

To display usage for the resource command

To display usage for the command `hares` and its various options:

```
hares [-help [-modify | -list]]
```
Administering clusters in global clusters

To add a remote cluster object

```bash
haclus -add cluster ip
```

The variable `cluster` represents the cluster. This command does not apply to the local cluster.

To delete a remote cluster object

```bash
haclus -delete cluster
```

The variable `cluster` represents the cluster.

To modify an attribute of a local or remote cluster object

```bash
haclus -modify attribute value [-clus cluster]...
```

The variable `cluster` represents the cluster.

To declare the state of a cluster after a disaster

```bash
haclus -declare disconnet/outage/disaster/replica -clus cluster [-failover]
```

The variable `cluster` represents the remote cluster.

To manage cluster alerts

- Run the `haalert` command to manage cluster alerts.

```bash
haalert -testfd
```

Generates a simulated "cluster fault" alert that is sent to the VCS engine and GUI.

```bash
haalert -display
```

For each alert, the command displays the following information:

- alert ID
- time when alert occurred
- cluster on which alert occurred
- object name for which alert occurred
- (cluster name, group name, and so on).
- informative message about alert

```bash
haalert -list
```

For each alert, the command displays the following information:

- time when alert occurred
- alert ID
Changing the cluster name

This section describes how to change the ClusterName in a global cluster configuration. The instructions describe how to rename VCSPriCluster to VCSPriCluster2 in a two-cluster configuration, comprising clusters VCSPriCluster and VCSSecCluster configured with the global group AppGroup.

Before changing the cluster name, make sure the cluster is not part of any ClusterList, in the wide-area Heartbeat agent and in global service groups.

To change the name of a cluster

1. Run the following commands from cluster VCSPriCluster:
   ```
   hagrp -offline ClusterService -any
   hagrp -modify AppGroup ClusterList -delete VCSPriCluster
   haclus -modify ClusterName VCSPriCluster2
   hagrp -modify AppGroup ClusterList -add VCSPriCluster2 0
   ```

2. Run the following commands from cluster VCSSecCluster:
   ```
   hagrp -offline ClusterService -any
   hagrp -modify appgrp ClusterList -delete VCSPriCluster
   hahb -modify Icmp ClusterList -delete VCSPriCluster
   haclus -delete VCSPriCluster
   haclus -add VCSPriCluster2 your_ip_address
   hahb -modify Icmp ClusterList -add VCSPriCluster2
   hahb -modify Icmp Arguments your_ip_address -clus VCSPriCluster2
   hagrp -modify AppGroup ClusterList -add VCSPriCluster2 0
   hagrp -online ClusterService -any
   ```

3. Run the following command from the cluster renamed to VCSPriCluster2:
   ```
   hagrp -online ClusterService -any
   ```
Administering heartbeats

To create a heartbeat

```
  habb -add heartbeat
```

For example, type the following command to add a new IcmpS heartbeat. This represents a heartbeat sent from the local cluster and immediately forks off the specified agent process on the local cluster.

```
  habb -add IcmpS
```

To modify a heartbeat

```
  habb -modify heartbeat attribute value ... [-clus cluster]
```

If the attribute is local, that is, it has a separate value for each remote cluster in the ClusterList attribute, the option `-clus cluster` must be specified. Use `-delete -keys` to clear the value of any list attributes.

For example, type the following command to modify the ClusterList attribute and specify targets “phoenix” and “houston” for the newly created heartbeat:

```
  habb -modify ICMP ClusterList phoenix houston
```

To modify the Arguments attribute for target phoenix:

```
  habb -modify ICMP Arguments phoenix.example.com -clus phoenix
```

To delete a heartbeat

```
  habb -delete heartbeat
```

To change the scope of an attribute to cluster-specific

```
  habb -local heartbeat attribute
```

For example, type the following command to change the scope of the attribute AYAInterval from global to cluster-specific:

```
  habb -local ICMP AYAInterval
```

To change the scope of an attribute to global

```
  habb -global heartbeat attribute value ...
      key ...  |  key value ...
```

For example, type the following command to change the scope of the attribute AYAInterval from cluster-specific to cluster-generic:

```
  habb -global ICMP AYAInterval 60
```
Setting up replicated data clusters

- About replicated data clusters
- How VCS replicated data clusters work
- Setting up a replicated data cluster configuration
About replicated data clusters

The Replicated Data Cluster (RDC) configuration provides both local high availability and disaster recovery functionality in a single VCS cluster. You can set up RDC in a VCS environment using Veritas Volume Replicator (VVR.)

A Replicated Data Cluster (RDC) uses data replication to assure data access to nodes. An RDC exists within a single VCS cluster. In an RDC configuration, if an application or a system fails, the application is failed over to another system within the current primary site. If the entire primary site fails, the application is migrated to a system in the remote secondary site (which then becomes the new primary).

For VVR replication to occur, the disk groups containing the Replicated Volume Group (RVG) must be imported at the primary and secondary sites. The replication service group must be online at both sites simultaneously, and must be configured as a hybrid VCS service group.

The application service group is configured as a failover service group. The application service group must be configured with an online local hard dependency on the replication service group.

**Note:** VVR supports multiple replication secondary targets for any given primary. However, RDC for VCS supports only one replication secondary for a primary.

An RDC configuration is appropriate in situations where dual dedicated LLT links are available between the primary site and the disaster recovery secondary site but lacks shared storage or SAN interconnect between the primary and secondary data centers. In an RDC, data replication technology is employed to provide node access to data in a remote site.

**Note:** You must use dual dedicated LLT links between the replicated nodes.
How VCS replicated data clusters work

To understand how a replicated data cluster configuration works, let us take the example of an application configured in a VCS replicated data cluster. The configuration has two system zones:

- Primary zone (zone 0) comprising nodes located at the primary site and attached to the primary storage
- Secondary zone (zone 1) comprising nodes located at the secondary site and attached to the secondary storage

The application is installed and configured on all nodes in the cluster. Application data is located on shared disks within each RDC zone and is replicated across RDC zones to ensure data concurrency. The application service group is online on a system in the current primary zone and is configured to fail over in the cluster.

In the event of a system or application failure, VCS attempts to fail over the application service group to another system within the same RDC zone. However, in the event that VCS fails to find a failover target node within the primary RDC zone, VCS switches the service group to a node in the current secondary RDC zone (zone 1). VCS also redirects clients once the application is online on the new location.
Setting up a replicated data cluster configuration

Depending on your application, refer to one of the following solutions guides for detailed configuration information:

- For Microsoft Exchange 2003, see the *Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide for Microsoft Exchange 2003*.

- For Microsoft Exchange 2007, see the *Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide for Microsoft Exchange 2007*.

- For Microsoft SQL Server 2000 or 2005, see the *Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide for Microsoft SQL Server*.

- For any other application, see the *Veritas Storage Foundation and High Availability Solutions HA and Disaster Recovery Solutions Guide*. 
Troubleshooting and performance

- Chapter 22, “Troubleshooting and recovery for VCS” on page 677
VCS performance considerations

- How cluster components affect performance
- How cluster operations affect performance
- Monitoring CPU usage
- VCS agent statistics
How cluster components affect performance

VCS and its agents run on the same systems as the applications. Therefore, VCS attempts to minimize its impact on overall system performance. The three main components of clustering that have an impact on performance include the kernel; specifically, GAB and LLT, the VCS engine (HAD), and the VCS agents. For details on attributes or commands mentioned in the following sections, see the chapter on administering VCS from the command line and the appendix on VCS attributes.

Kernel components (GAB and LLT)

Typically, overhead of VCS kernel components is minimal. Kernel components provide heartbeat and atomic information exchange among cluster systems. By default, each system in the cluster sends two small heartbeat packets per second to other systems in the cluster. Heartbeat packets are sent over all network links configured in the following LLT configuration file:

%VCS_HOME%\comms\llt\llttab.txt

System-to-system communication is load-balanced across all private network links. If a link fails, VCS continues to use all remaining links. Typically, network links are private and do not increase traffic on the public network or LAN. You can configure a public network (LAN) link as low-priority, which by default generates a small (approximately 64-byte) broadcast packet per second from each system, and which will carry data only when all private network links have failed.
The VCS engine (HAD)

The VCS engine, HAD, runs as a daemon process. By default it runs as a high-priority process, which ensures it sends heartbeats to kernel components and responds quickly to failures. HAD runs logging activities in a separate thread to reduce the performance impact on the engine due to logging.

VCS waits in a loop waiting for messages from agents, ha commands, the graphical user interfaces, and the other systems. Under normal conditions, the number of messages processed by HAD is few. They mainly include heartbeat messages from agents and update messages from the global counter. VCS may exchange additional messages when an event occurs, but typically overhead is nominal even during events. Note that this depends on the type of event; for example, a resource fault may involve taking the group offline on one system and bringing it online on another system. A system fault invokes failing over all online service groups on the faulted system.

To continuously monitor VCS status, use the VCS graphical user interfaces or the command hastatus. Both methods maintain connection to VCS and register for events, and are more efficient compared to running commands like hastatus -summary or hasys in a loop.

The number of clients connected to VCS can affect performance if several events occur simultaneously. For example, if five GUI processes are connected to VCS, VCS sends state updates to all five. Maintaining fewer client connections to VCS reduces this overhead.

How agents impact performance

The VCS agent processes have the most impact on system performance. Each agent process has two components: the agent framework and the agent functions. The agent framework provides common functionality, such as communication with the HAD, multithreading for multiple resources, scheduling threads, and invoking functions. Agent functions implement agent-specific functionality. Follow the performance guidelines below when configuring agents.

Monitoring resource type and agent configuration

By default, VCS monitors each resource every 60 seconds. You can change this by modifying the MonitorInterval attribute for the resource type. You may consider reducing monitor frequency for non-critical or resources with expensive monitor operations. Note that reducing monitor frequency also means that VCS may take longer to detect a resource fault.

By default, VCS also monitors offline resources. This ensures that if someone brings the resource online outside of VCS control, VCS detects it and flags a
VCS performance considerations

How cluster components affect performance

concurrency violation for failover groups. To reduce the monitoring frequency of offline resources, modify the OfflineMonitorInterval attribute for the resource type.

The VCS agent framework uses multithreading to allow multiple resource operations to run in parallel for the same type of resources. For example, a single Mount agent handles all mount resources. The number of agent threads for most resource types is 10 by default. To change the default, modify the NumThreads attribute for the resource type. The maximum value of the NumThreads attribute is 30.

Continuing with this example, the Mount agent schedules the monitor function for all mount resources, based on the MonitorInterval or OfflineMonitorInterval attributes. If the number of mount resources is more than NumThreads, the monitor operation for some mount resources may be required to wait to execute the monitor function until the thread becomes free.

Additional considerations for modifying the NumThreads attribute include:

■ If you have only one or two resources of a given type, you can set NumThreads to a lower value.

■ If you have many resources of a given type, evaluate the time it takes for the monitor function to execute and the available CPU power for monitoring. For example, if you have 50 mount points, you may want to increase NumThreads to get the ideal performance for the Mount agent without affecting overall system performance.

You can also adjust how often VCS monitors various functions by modifying their associated attributes. The attributes MonitorTimeout, OnlineTimeOut, and OfflineTimeout indicate the maximum time (in seconds) within which the monitor, online, and offline functions must complete or else be terminated. The default for the MonitorTimeout attribute is 60 seconds. The defaults for the OnlineTimeout and OfflineTimeout attributes is 300 seconds. For best results, Symantec recommends measuring the time it takes to bring a resource online, take it offline, and monitor before modifying the defaults. Issue an online or offline command to measure the time it takes for each action. To measure how long it takes to monitor a resource, fault the resource and issue a probe, or bring the resource online outside of VCS control and issue a probe.

Agents typically run with normal priority. When you develop agents, consider the following:

■ If you write a custom agent, write the monitor function using C or C++. If you write a script-based monitor, VCS must invoke a new process each time with the monitor. This can be costly if you have many resources of that type.

■ If monitoring the resources is proving costly, you can divide it into cursory, or shallow monitoring, and the more extensive deep (or in-depth)
monitoring. Whether to use shallow or deep monitoring depends on your configuration requirements.

**Additional considerations for agents**

Properly configure the attribute SystemList for your service group. For example, if you know that a service group can go online on sysa and sysb only, *do not* include other systems in the SystemList. This saves additional agent processes and monitoring overhead.

**The VCS graphical user interfaces**

The VCS graphical user interfaces, Cluster Manager (Java Console) and Cluster Management Console maintain a persistent connection to HAD, from which they receive regular updates regarding cluster status. For best results, run the GUIs on a system outside the cluster to avoid impact on node performance.
How cluster operations affect performance

This section describes how operations on systems, resources, and service groups in the cluster affect performance.

Booting a cluster system

When a cluster system boots, the kernel drivers and VCS process start in a particular order. If it is the first system in the cluster, VCS reads the cluster configuration file main.cf and builds an "in-memory configuration database. This is the LOCAL_BUILD state. After building the configuration database, the system transitions into the RUNNING mode. If another system joins the cluster while the first system is in the LOCAL_BUILD state, it must wait until the first system transitions into RUNNING mode. The time it takes to build the configuration depends on the number of service groups in the configuration and their dependencies, and the number of resources per group and resource dependencies. VCS creates an object for each system, service group, type, and resource. Typically, the number of systems, service groups and types are few, so the number of resources and resource dependencies determine how long it takes to build the configuration database and get VCS into RUNNING mode. If a system joins a cluster in which at least one system is in RUNNING mode, it builds the configuration from the lowest-numbered system in that mode.

Note: Bringing service groups online as part of AutoStart occurs after VCS transitions to RUNNING mode.

When a resource comes online

The online function of an agent brings the resource online. This function may return before the resource is fully online. The subsequent monitor determines if the resource is online, then reports that information to VCS. The time it takes to bring a resource online equals the time for the resource to go online, plus the time for the subsequent monitor to execute and report to VCS.

Most resources are online when the online function finishes. The agent schedules the monitor immediately after the function finishes, so the first monitor detects the resource as online. However, for some resources, such as a database server, recovery can take longer. In this case, the time it takes to bring a resource online depends on the amount of data to recover. It may take multiple monitor intervals before a database server is reported online. When this occurs, it is important to have the correct values configured for the OnlineTimeout and OnlineWaitLimit attributes of the database server resource type.
When a resource goes offline

Similar to the online function, the offline function takes the resource offline and may return before the resource is actually offline. Subsequent monitoring confirms whether the resource is offline. The time it takes to offline a resource equals the time it takes for the resource to go offline, plus the duration of subsequent monitoring and reporting to VCS that the resource is offline. Most resources are typically offline when the offline function finishes. The agent schedules the monitor immediately after the offline function finishes, so the first monitor detects the resource as offline.

When a service group comes online

The time it takes to bring a service group online depends on the number of resources in the service group, the service group dependency structure, and the time to bring the group’s resources online. For example, if service group G1 has three resources, R1, R2, and R3 (where R1 depends on R2 and R2 depends on R3), VCS first onlines R3. When R3 is online, VCS onlines R2. When R2 is online, VCS onlines R1. The time it takes to online G1 equals the time it takes to bring all resources online. However, if R1 depends on both R2 and R3, but there was no dependency between them, the online operation of R2 and R3 is started in parallel. When both are online, R1 is brought online. The time it takes to online the group is Max (the time to online R2 and R3), plus the time to online R1. Typically, broader service group trees allow more parallel operations and can be brought online faster. More complex service group trees do not allow much parallelism and serializes the group online operation.

The time it takes to bring a service group online or take it offline also depends on the type of service group, such as fileshare, printshare, enterprise agent, etc. For a fileshare service group, there are four factors that determine how long it takes to bring a fileshare online:

- **ShareSubDirectories**
  If set to 1, each child subdirectory is shared. the fileshare group’s online entry point shares child folders in addition to parent folders.

- **Number of subdirectories**
  The greater the number of subdirectories being shared, the longer it takes to bring online, monitor, and take offline a fileshare service group.

- **Number of permissions**
  For each share, the online entry point applies the share permissions as configured.

- **AutoShare and AutoControl**
By default, if ShareSubDirectories is set, the fileshare service group monitors new directories and shares them. AutoShare occurs in the monitor entry points.

For a printshare service group, the number of printers configured in the service group determines the time required for the service group to come online. The greater the number of printers, the more time required to bring the group online, monitor it, and take it offline.

When a service group goes offline

Taking service groups offline works from the top down, as opposed to the online operation, which works from the bottom up. The time it takes to offline a service group depends on the number of resources in the service group and the time to offline the group’s resources. For example, if service group G1 has three resources, R1, R2, and R3, VCS first offlines R1. When R1 is offline, VCS offlines R2. When R2 is offline, VCS offlines R3. The time it takes to offline G1 equals the time it takes for all resources to go offline.

When a resource fails

The time it takes to detect a resource fault or failure depends on the MonitorInterval attribute for the resource type. When a resource faults, the next monitor detects it. The agent may not declare the resource as faulted if the ToleranceLimit attribute is set to non-zero. If the monitor function reports offline more often than the number set in ToleranceLimit, the resource is declared faulted. However, if the resource remains online for the interval designated in the ConfInterval attribute, previous reports of offline are not counted against ToleranceLimit.

When the agent determines that the resource is faulted, it calls the clean function (if implemented) to verify that the resource is completely offline. The monitor following clean verifies the offline. The agent then tries to restart the resource according to the number set in the RestartLimit attribute (if the value of the attribute is non-zero) before it gives up and informs HAD that the resource is faulted. However, if the resource remains online for the interval designated in ConfInterval, earlier attempts to restart are not counted against RestartLimit.

In most cases, ToleranceLimit is 0. The time it takes to detect a resource failure is the time it takes the agent monitor to detect failure, plus the time to clean up the resource if the clean function is implemented. Therefore, the time it takes to detect failure depends on the MonitorInterval, the efficiency of the monitor and clean (if implemented) functions, and the ToleranceLimit (if set).
When a system fails

When a system crashes or is powered off, it stops sending heartbeats to other systems in the cluster. By default, other systems in the cluster wait 21 seconds before declaring it dead. The time of 21 seconds derives from 16 seconds default value for LLT peer inactive timeout, plus 5 seconds default value for GAB stable timeout. The default peer inactive timeout is 16 seconds, and can be modified in the %VCS_HOME%\comms\llt\llttab.txt file. For example, to specify 12 seconds:

```
set-timer peerinact:1200
```

Note: After modifying the peer inactive timeout, you must unconfigure, then restart LLT before the change is implemented. To unconfigure LLT, type lltconfig -u. To restart LLT, type lltconfig -c.

GAB stable timeout can be changed by specifying:

```
gabconfig -t timeout_value_milliseconds
```

Though this can be done, we do not recommend changing the values of the LLT peer inactive timeout and GAB stable timeout.

If a system boots, it becomes unavailable until the reboot is complete. The reboot process kills all processes, including HAD. When the VCS process is killed, other systems in the cluster mark all service groups that can go online on the rebooted system as autodisabled. The AutoDisabled flag is cleared when the system goes offline. As long as the system goes offline within the interval specified in the ShutdownTimeout value, VCS treats this as a system reboot. The ShutdownTimeout default value can be changed by modifying the attribute. See “System attributes” on page 779.

When a network link fails

If a system loses a network link to the cluster, other systems stop receiving heartbeats over the links from that system. LLT detects this failure and waits for 16 seconds (default value for LLT peer inactive timeout) before declaring that the system lost a link.

You can modify the LLT peer inactive timeout value in the /etc/llttab file. For example, to specify 12 seconds:

```
set-timer peerinact:1200
```

Note: After modifying the peer inactive timeout, you must unconfigure, then restart LLT before the change is implemented. To unconfigure LLT, type lltconfig -u. To restart LLT, type lltconfig -c.
When a system panics

There are several instances in which GAB will intentionally panic a system, including if it detects an internal protocol error or discovers an LLT node-ID conflict. Under severe load conditions, if VCS cannot heartbeat with GAB, it may induce a panic or a VCS restart.

This section describes the scenarios when GAB panics a system.

Client process failure

If a client process fails to heartbeat to GAB, the process is killed. If the process hangs or cannot be killed, GAB halts the system. This could also occur if the node is overloaded and HAD cannot run on the node.

If the -k option is used in the `gabconfig` command, GAB tries to kill the client process until successful, which may have an impact on the entire cluster. If the -b option is used in `gabconfig`, GAB does not try to kill the client process. Instead, it panics the system when the client process fails to heartbeat. This option cannot be turned off once set.

HAD heartbeats with GAB at regular intervals. The heartbeat timeout is specified by HAD when it registers with GAB; the default is 15 seconds. If HAD gets stuck within the kernel and cannot heartbeat with GAB within the specified timeout, GAB tries to kill HAD by sending a SIGABRT signal. If it does not succeed, GAB sends a SIGKILL and closes the port. By default, GAB tries to kill HAD five times before closing the port. The number of times GAB tries to kill HAD is a kernel tunable parameter, `gab_kill_ntries`, and is configurable. The minimum value for this tunable is 3 and the maximum is 10.

This is an indication to other nodes that HAD on this node has been killed. Should HAD recover from its stuck state, it first processes pending signals. Here it will receive the SIGKILL first and get killed.

After sending a SIGKILL, GAB waits for a specific amount of time for HAD to get killed. If HAD survives beyond this time limit, GAB panics the system. This time limit is a kernel tunable parameter, `gab_isolate_time` and is configurable. The minimum value for this timer is 16 seconds and maximum is 4 minutes.

Registration monitoring

The registration monitoring features lets you configure GAB behavior when HAD is killed and does not reconnect after a specified time interval.

This scenario may occur in the following situations:

- The system is very busy and the hashadow process cannot restart HAD.
- The HAD and hashadow processes were killed by user intervention.
- The hashadow process restarted HAD, but HAD could not register.
A hardware/DIMM failure caused termination of the HAD and hashadow processes.

Any other situation where the HAD and hashadow processes are not run. When this occurs, the registration monitoring timer starts. GAB takes action if HAD does not register within the time defined by the VCS_GAB_RMTIMEOUT parameter, which is defined in the vcsenv file. The default value for VCS_GAB_RMTIMEOUT is 200 seconds.

When HAD cannot register after the specified time period, GAB logs a message every 15 seconds saying it will panic the system.

You can control GAB behavior in this situation by setting the VCS_GAB_RMACTION environment variable.

To configure GAB to panic the system in this situation, set:

VCS_GAB_RMACTION=panic

In this configuration, killing the HAD and hashadow processes results in a panic unless you start HAD within the registration monitoring timeout interval.

To configure GAB to log a message in this situation, set:

VCS_GAB_RMACTION=SYSLOG

The default value of this parameter is SYSLOG, which configures GAB to log a message when HAD does not reconnect after the specified time interval. In this scenario, you can choose to restart HAD (using hastart) or restart the GAB service.

When you enable registration monitoring, GAB takes no action if the HAD process unregisters with GAB normally, that is if you stop HAD using the hastop command.

Network failure

If a network partition occurs, a cluster can “split into two or more separate sub-clusters. When two clusters join as one, VCS designates that one system be ejected. GAB prints diagnostic messages and sends iofence messages to the system being ejected. The system receiving the iofence messages tries to kill the client process. The -k option applied here. If the -j option is used in gabconfig, the system is halted when the iofence message is received.

Quick reopen

If a system leaves the cluster and tries to join the cluster before the new cluster is configured (default is five seconds), the system is sent an iofence message with reason set to “quick reopen. When the system receives the message, it tries to kill the client process.
When a service group switches over

The time it takes to switch a service group equals the time to offline a service group on the source system, plus the time to bring the service group online on the target system.

When a service group fails over

The time it takes to fail over a service group when a resource faults equals

- the time it takes to detect the resource fault
- the time it takes to offline the service group on source system
- the time it takes for the VCS policy module to select target system
- the time it takes to bring the service group online on target system

The time it takes to fail over a service group when a system faults equals

- the time it takes to detect system fault
- the time it takes to offline the service group on source system
- the time it takes for the VCS policy module to select target system
- the time it takes to bring the service group online on target system

The time it takes the VCS policy module to determine the target system is negligible in comparison to the other factors.

If you have a firm group dependency and the child group faults, VCS offlines all immediate and non-immediate parent groups before bringing the child group online on the target system. Therefore, the time it takes a parent group to be brought online also depends on the time it takes the child group to be brought online.

Monitoring CPU usage

VCS includes a system attribute, CPUUsageMonitoring, which monitors CPU usage on a specific system and notifies the administrator when usage has been exceeded.

The default values for the CPUUsageMonitoring attribute are:

- Enabled = 0
- NotifyThreshold = 0
- NotifyTimeLimit = 0
- ActionThreshold = 0
- ActionTimeLimit = 0
- Action = NONE.

The values for ActionTimeLimit and NotifyTimeLimit represent the time in seconds. The values for ActionThreshold and NotifyThreshold represent the threshold in terms of CPU percentage utilization.

If Enabled is set to 1, HAD monitors the usage and updates CPUUsage attribute. If Enabled is set to 0 (default), HAD does not monitor the usage.

If the system’s CPU usage continuously exceeds the value set in NotifyThreshold for a duration greater than the value set in NotifyTimeLimit, HAD sends notification via an SNMP trap or SMTP message.

If the CPU usage continuously exceeds the value set in NotifyThreshold for a duration greater than the value set in NotifyTimeLimit, subsequent notifications are sent after five minutes to avoid sending notifications too frequently (if the NotifyTimeLimit value is set to a value less than five minutes). In this case, notification is sent after the first interval of NotifyTimeLimit. As CPU usage continues to exceed the threshold value, notifications are sent after five minutes. If the values of NotifyThreshold or NotifyTimeLimit are set to 0, no notification is sent.

If system’s CPU usage exceeds the value set in ActionThreshold continuously for a duration greater than the value set in ActionTimeLimit, the specified action is taken. If the CPU usage continuously exceeds the ActionThreshold for a duration greater than the value set in ActionTimeLimit, subsequent action is taken after five minutes to avoid taking action too frequently (if the ActionTimeLimit value is set to less than five minutes). In this case action is taken after the first interval of ActionTimeLimit. As CPU usage continues to exceed the threshold value, action is taken after five minutes. If the values of ActionThreshold or ActionTimeLimit are set to 0, no action is taken. Actions can have one of the following values:
NONE: No action will be taken and the message is logged in the VCS engine log.
REBOOT: System is rebooted.
CUSTOM: The cpuusage trigger is invoked.

VCS agent statistics

You can configure VCS to track the time taken for monitoring resources. You can also detect potential problems with resources and systems on which resources are online by analyzing the trends in the time taken by the resource's monitor cycle. Note that VCS keeps track of monitor cycle times for online resources only.

VCS calculates the time taken for a monitor cycle to complete and computes an average of monitor times after a specific number of monitor cycles and stores the average in a resource-level attribute.

VCS also tracks increasing trends in the monitor cycle times and sends notifications about sudden and gradual increases in monitor times.

VCS uses the following parameters to compute the average monitor time and to detect increasing trends in monitor cycle times:

- **Frequency**: The number of monitor cycles after which the monitor time average is computed and sent to the VCS engine. For example, if Frequency is set to 10, VCS computes the average monitor time after every 10 monitor cycles.

- **ExpectedValue**: The expected monitor time (in milliseconds) for a resource. VCS sends a notification if the actual monitor time exceeds the expected monitor time by the ValueThreshold. So, if you set this attribute to 5000 for a FileOnOff resource, and if ValueThreshold is set to 40%, VCS will send a notification only when the monitor cycle for the FileOnOff resource exceeds the expected time by over 40%, that is 7000 milliseconds.

- **ValueThreshold**: The maximum permissible deviation (in percent) from the expected monitor time. When the time for a monitor cycle exceeds this limit, VCS sends a notification about the sudden increase or decrease in monitor time. For example, a value of 100 means that VCS sends a notification if the actual monitor time deviates from the expected time by over 100%. VCS sends these notifications conservatively. If 12 consecutive monitor cycles exceed the threshold limit, VCS sends a notification for the first spike, and then a collective notification for the next 10 consecutive spikes.

- **AvgThreshold**: The threshold value (in percent) for increase in the average monitor cycle time for a resource.
VCS maintains a running average of the time taken by the monitor cycles of a resource. The first such computed running average is used as a benchmark average. If the current running average for a resource differs from the benchmark average by more than this threshold value, VCS regards this as a sign of gradual increase or decrease in monitor cycle times and sends a notification about it for the resource. Whenever such an event occurs, VCS resets the internally maintained benchmark average to this new average. VCS sends notifications regardless of whether the deviation is an increase or decrease in the monitor cycle time.

For example, a value of 25 means that if the actual average monitor time is 25% more than the benchmark monitor time average, VCS sends a notification.

Tracking monitor cycle times

VCS marks sudden changes in monitor times by comparing the time taken for each monitor cycle with the ExpectedValue. If this difference exceeds the ValueThreshold, VCS sends a notification about the sudden change in monitor time. Note that VCS sends this notification only if monitor time increases.

VCS marks gradual changes in monitor times by comparing the benchmark average and the moving average of monitor cycle times. VCS computes the benchmark average after a certain number of monitor cycles and computes the moving average after every monitor cycle. If the current moving average exceeds the benchmark average by more than the AvgThreshold, VCS sends a notification about this gradual change in the monitor cycle time.
VCS attributes enabling agent statistics

This section describes the attributes that enable VCS agent statistics.

MonitorStatsParam A resource type-level attribute, which stores the required parameter values for calculating monitor time statistics.

```csharp
static str MonitorStatsParam = { Frequency = 10, ExpectedValue = 3000, ValueThreshold = 100, AvgThreshold = 40 }
```

- **Frequency**: Defines the number of monitor cycles after which the average monitor cycle time should be computed and sent to the engine. If configured, the value for this attribute must be between 1 and 30. It is set to 0 by default.

- **ExpectedValue**: The expected monitor time in milliseconds for all resources of this type. Default=3000.

- **ValueThreshold**: The acceptable percentage difference between the expected monitor cycle time (ExpectedValue) and the actual monitor cycle time. Default=100.

- **AvgThreshold**: The acceptable percentage difference between the benchmark average and the moving average of monitor cycle times. Default=40

MonitorTimeStats Stores the average time taken by a number of monitor cycles specified by the Frequency attribute along with a timestamp value of when the average was computed.

```csharp
str MonitorTimeStats() = { Avg = "0", TS = "" }
```

This attribute is updated periodically after a number of monitor cycles specified by the Frequency attribute. If Frequency is set to 10, the attribute stores the average of 10 monitor cycle times and is updated after every 10 monitor cycles.

The default value for this attribute is 0.

ComputeStats A flag that specifies whether VCS keeps track of the monitor times for the resource.

```csharp
bool ComputeStats = 0
```

The value 0 indicates that VCS will not keep track of the time taken by the monitor routine for the resource. The value 1 indicates that VCS keeps track of the monitor time for the resource.

The default value for this attribute is 0.
VCS performance with non-HA products

To ensure optimum performance, it is important to evaluate the impact of non-HA products on cluster nodes. Evaluating factors such as the complexity of the VCS configuration, the capacity of the hardware to host multiple applications, and the intended use of the product will assist you in determining how and where to host the applications.

When modifying the system, consider whether or not the change will cause the service group to fault. A simple task such as Windows Explorer browsing fileshares hosted by VCS may seem harmless, but it would prevent VCS from failing over because the drive is locked by another application.

VCS performance with SFW

If you use Veritas Storage Foundation for Windows (SFW) on clustered nodes, we strongly recommend the following:

- Carefully evaluate changes to underlying storage. Typically, changes to the volume and disk group configurations require corresponding changes to the VCS configuration. Common changes include unassigning or reassigning the drive letters, splitting or joining a disk group, or snapshotting the volume. Prior to implementing these types of changes, evaluate your configuration to determine whether to freeze, offline, or fail over the VCS service groups to avoid faulting the groups inadvertently.

- Like Cluster Manager, the SFW GUI runs under the Java Runtime environment and maintains a persistent connection to the SFW engine, from which it receives regular updates regarding status. For best results, run the SFW GUI on a system outside the cluster. This will avoid potential impact on node performance.

- Certain SFW operations, such as rescan, resync, etc., are CPU-intensive and can affect VCS performance. The VCS kernel module GAB expects the VCS engine, HAD, to send heartbeats that ensure the engine is functioning properly. If the heartbeat interval exceeds five seconds the engine logs an error.

By default, if GAB does not receive a heartbeat from HAD within 15 seconds, GAB assumes something is wrong and kills HAD (which then gets restarted by hashadow). You can tune this interval by changing the value of the system variable VCS_GAB_TIMEOUT, which specifies the number of seconds GAB waits for a heartbeat before killing HAD.

About troubleshooting and recovery for VCS

This chapter explains VCS unified logging and defines the message format. This chapter also describes how to troubleshoot common problems.

Logging

VCS generates two error message logs: the engine log and the agent log. Log file names are appended by letters. Letter A indicates the first log file, B the second, C the third, and so on.

The engine log is located at %VCS_HOME%\log\engine_A.txt. The format of engine log messages is:

```
Timestamp (Year/MM/DD) | Mnemonic | Severity | UMI | Message Text
```

The agent log components are defined as follows:

- **Timestamp**: the date and time the message was generated.
- **Mnemonic**: the string ID that represents the product (for example, VCS).
- **Severity**: levels include CRITICAL, ERROR, WARNING, NOTICE, and INFO (most to least severe, respectively).
- **UMI**: a unique message ID.
- **Message Text**: the actual message generated by VCS.

A typical engine log resembles:

```
2003/02/10 16:08:09 VCS INFO V-16-1-10077 received new cluster membership.
```

The agent log is located at %VCS_HOME%\log\agent_A.txt. The format of agent log messages is:

```
Timestamp (Year/MM/DD) | Mnemonic | Severity | UMI | Agent Type | Resource Name | Entry Point | Message Text
```

A typical agent log resembles:

2003/02/23 10:38:23 VCS WARNING V-16-2-23331
Oracle:VRT:monitor:Open for ora_lgwr failed, setting cookie to null.

VCW logs

The VCS Cluster Configuration Wizard (VCW) log is located at
%allusersprofile%\Application Data\Veritas\Cluster
Server\vcw.log.

Here, %allusersprofile% is the file system directory containing application
data for all users. A typical path is C:\Documents and Settings\All
Users\.

The format of the VCW log is

<table>
<thead>
<tr>
<th>ThreadID</th>
<th>Message Text</th>
</tr>
</thead>
</table>

- **ThreadID**: the ID of the thread initiated by VCW.
- **Message Text**: the actual message generated by VCW.

A typical VCW log resembles:

00000576-00000264: ExecMethod return 00000000.
00000576-00000110: CRegistry::Query for VCS License failed.
  Error=0x00000000
00000576-00000264: ExecMethod return 00000000.
00000576-00000264: ExecMethod return 00000001.
00000576-00000127: QueryDWORDValue returned 0x00000001
00000576-00000132: CRegistry::Query for VxSS Root information
  failed. Error=0x00000001

VCWsilent logs

The VCWsilent log is located at <currentdirectory>\vcwsilent.log.

Here, <currentdirectory> is the directory from where the VCWsilent.exe is run.

A typical VCWsilent log resembles:

00005540-00000064: 5540: STARTING - Discovering NICs on the
  selected machines...
00009956-00000064: 9956: STARTING - Generating private network
  related files...
00009956-00000048: 9956: COMPLETED - Generating LLT host
  files...
00009956-00000048: 9956: COMPLETED - Generating GAB tab files...
00009956-00000048: 9956: COMPLETED - Generating main.cf file...
00009956-00000064: 9956: STARTING - Configuring LLT on all the
  nodes.
00009956-00000048: 9956: COMPLETED - Configuring LLT on all the
  nodes.
Solutions wizard logs

The Solutions Configuration Center provides access to many wizards. However, three wizards are built in to the Solutions Configuration Center:

- Disaster Recovery Wizard
- Fire Drill Wizard
- Quick Recovery Configuration Wizard

These three Solutions wizards are launched only from the Solutions Configuration Center, whereas other wizards can be launched from product consoles or the Start menu.

Logs created by these three Solutions wizards are located in the following paths:

**For Windows Server 2003:**

C:\Documents and Settings\All Users\Application Data\VERITAS\winsolutions\log

**For Windows Server 2008:**

C:\ProgramData\Veritas\winsolutions\log

Message catalogs

VCS includes multilingual support for message catalogs. Most binary message catalogs (BMCs), are stored in %VCS_HOME%\messages\language\. The catalogs ggb.bmc and llt.bmc are stored in %VCS_ROOT%\comms\messages\language\. The variable language represents a two-letter abbreviation. For example, en represents English.

The VCS command-line interface displays error/success messages in any language supported by VCS. The hamsg command displays the VCS engine logs in VCS-supported languages.

The following table shows the complete list of BMCs.

**Table 22-1**  Binary message catalogs

Handling network failure

VCS protects against network partitions by requiring that all systems be connected by two or more communication channels. In a VCS cluster, all systems send heartbeats to each other across communication channels. If a system’s heartbeats are not received across one channel, VCS detects that the channel has failed. If a system’s heartbeats are not received across any channels, VCS detects that the system has failed. The services running on that system are then restarted on another.

VCS continues to operate as a single cluster when at least one network channel exists between the systems. However, when only one channel remains, failover due to system failure is disabled. Even after the last network connection is lost, VCS continues to operate as partitioned clusters on each side of the failure. For more information on protecting your cluster against network failure, see “Verifying LLT, GAB, and cluster operation” on page 691.

Disabling failover

When VCS loses communication with a system, a new regular membership is issued that excludes the departed system. VCS must then determine if it should restart that system’s services, or if the system is running services outside of communication with VCS. Two conditions indicate that the system could still be running the services:

- Prior to the system’s departure, the systems remaining in the new membership were connected to the departed system by only one communication channel.
- The departed system continues writing heartbeats to disk. VCS detects these conditions using the jeopardy membership.

If there is at least one system in the new regular membership that was not part of the prior jeopardy membership, then failover is disabled only for those systems that left the regular membership and were part of the prior jeopardy membership. Failover is also disabled for systems that are in the new jeopardy membership and outside of the new regular membership. This indicates these systems are actively writing heartbeats to disk. If there are no systems in the new regular membership that were not part of the previous jeopardy membership, failover is disabled for all systems that have departed. This indicates that connections from the remaining systems to all systems in the prior regular membership were potentially unreliable.
Example of how VCS handles network failure

In the following example, a single cluster has two networks connecting four nodes.

**Figure 22-1**  VCS and network failure: Four node cluster

![Diagram of a four node cluster with two networks connecting them. The regular membership is 0, 1, 2, 3.]

**Jeopardy scenario: link failure**

In this scenario, a link to node 2 fails, leaving the node with only one possible heartbeat.

**Figure 22-2**  VCS and network failure: Link to node 2 fails.

![Diagram of the same four node cluster as in Figure 22-1, with one link to node 2 removed. The regular membership is 0, 1, 2, 3, and the jeopardy membership is 2.]
A new cluster membership is issued with nodes 0, 1, 2, and 3 in the regular membership and node 2 in a jeopardy membership. All normal cluster operations continue, including normal failover of service groups due to resource fault.

Jeopardy scenario: link and node failure
Consider that in the previous link-failure scenario, node 2 fails due to a power fault.

Figure 22-3  VCS and network failure: Node 2 in jeopardy membership

All other systems recognize that node 2 has faulted. In this situation, a new membership is issued for nodes 0, 1 and 3 as regular members. Since node 2 was in a jeopardy membership, service groups running on node 2 are autodisabled, so no other node can assume ownership of these service groups. If the node is actually failed, the system administrator can clear the AutoDisabled flag on the service groups in question and online the groups on other systems in the cluster.
**Jeopardy scenario: failure of all links**

In the scenario depicted in the illustration below, node 2 loses both heartbeats.

**Figure 22-4**  VCS and network failure: Node 2 forms a single-node-mini cluster

![Diagram showing network failure](image)

In this situation, a new membership is issued for node 0, 1 and 3 as regular members. Since node 2 was in a jeopardy membership, service groups running on node 2 are autodisabled, so no other node can assume ownership of these service groups. Nodes 0, 1 and 3 form a mini-cluster. Node 2 forms another single-node mini-cluster. All service groups that were present on nodes 0, 1 and 3 are autodisabled on node 2.
Network partitioning

With VCS, two or more communication channels guard against network partitioning; a condition where a failure on the network is misinterpreted as a failure of one or more systems in the cluster. If one system in the cluster assumes wrongly that another system has failed, it may restart applications already running on the other system, thereby corrupting the data.

Using a second communication channel enables VCS to distinguish between network and system failures. If all but one network channel fails, VCS enters a degraded mode that disables automatic application failover caused by system failure. If the last network channel fails, VCS splits into multiple “mini-clusters” without failing over or shutting down applications. This design enables administrative services to operate uninterrupted; for example, you can use VCS to shut down applications during system maintenance. When connections are restored, systems will attempt to rejoin into a single cluster. By default, GAB kills processes associated with ports on rejoined systems. To avoid potential data corruption during rejoin, add the option -j to the gabconfig command to enable system halt after a split. The gabconfig command is located in %VCS_ROOT%\comms\gab.

When VCS shuts down a system

In some cases, VCS kernel components may intentionally bring down a system to avoid network partitioning. See the Veritas Cluster Server Release Notes for details.

Preexisting network partitions

A preexisting network partition refers to failures in communication channels that occur while the systems are down. Regardless of whether the cause is scheduled maintenance or system failure, VCS cannot respond to failures when systems are down. This leaves VCS vulnerable to network partitioning when the systems are booted. VCS seeding is designed to help prevent this situation.
VCS seeding

To protect your cluster from a pre-existing network partition, VCS employs the concept of a seed. Systems can be seeded automatically or manually. Note that only systems that have been seeded can run VCS.

By default, when a system comes up, it is not seeded. When the last system in a cluster is booted, the cluster will seed and start VCS on all systems. Systems can then be brought down and restarted in any combination. Seeding is automatic as long as at least one instance of VCS is running in the cluster.

Systems are seeded automatically in one of two ways:

- When an unseeded system communicates with a seeded system.
- When all systems in the cluster are unseeded and able to communicate with each other.

VCS requires that you declare the number of systems that will participate in the cluster.

When the last system is booted, the cluster will seed and start VCS on all systems. Systems can then be brought down and restarted in any combination. Seeding is automatic as long as at least one instance of VCS is running somewhere in the cluster.

Note that before VCS can accept HA commands, the cluster nodes must be seeded. If the nodes are not seeded and you attempt to issue a command, you receive the error message:

```
VCS:11037:Node has not received cluster membership yet, cannot process HA command
```

To seed a cluster

1. Verify the value of gabconfig -c in the file
   \%VCS_ROOT\comms\gab\gabtab.txt is the same for all nodes.
2. Determine how many nodes are operational.
3. For each cluster node, modify gabtab.txt to reflect the required number of members to seed are equal to the number of cluster nodes in operation.
4. Reboot each node, or stop HAD -force on all nodes and restart.
Troubleshooting and recovery for VCS

Handling network failure

Editing gabtab.txt after installing on a two-system cluster

In the unlikely event that the private network links fail, the -c -x option to the
gabconfig command makes it possible to bring up VCS on a subset of cluster
nodes. For an unseeded cluster, the -x option seeds the cluster, thus eliminating
the requirement that all nodes are seeded before the cluster is brought up.

Note: Because the subset of nodes on which VCS was restarted maintains access
to the disk and cannot communicate with the other cluster subset (which also
has access to the disk), this option must be used with caution to avoid data
corruption.

Reconnecting the private network

When a final network connection is lost, the systems on each side of the network
partition segregate into mini-clusters.

Reconnecting a private network after a cluster has been segregated causes HAD
to stop and restart. There are several rules that determine which systems will be
affected.

■ On a two-node cluster, the system with the lowest LLT host ID stays running
and the higher recycles HAD.

■ In a multi-node cluster, the largest running group stays running. The
smaller groups recycle HAD.

■ On a multi-node cluster splitting into two equal size clusters, the cluster
with the lowest node number stays running. The higher group recycles HAD.
Troubleshooting VCS startup

When VCS is started, GAB, LLT, and HAD are started automatically. If they are not, review the corresponding log file. Startup errors for LLT and GAB are stored in the System Event log. Startup errors for HAD are stored in the Application Event log.

To view log files
1. From the Control Panel, double-click Administrative Tools, then Event Viewer.
2. Review the System Log to view LLT and GAB errors.
3. Review the Application Log to view HAD errors.

Low Latency Transport (LLT)

During installation, an llttab.txt configuration file containing minimum directives is created and placed in the following directory on each node in the cluster:

```
Drive:\Program Files\VERITAS\comms\llt
```

Each llttab.txt file specifies the node’s ID, the network interfaces to use, and other directives. The most common LLT directives are listed on page 690.

Note: The directives must always appear as they are listed in the original default llttab.txt file.
Troubleshooting and recovery for VCS

Troubleshooting VCS startup

Common LLT directives

link Attaches LLT to a network interface. At least one link is required, and up to eight are supported. The first argument to link is a user-defined tag shown in the lltstat output to identify the link. It may also be used in llttab.txt to set optional static MAC addresses.

The second argument to link is the device name of the network interface. (To obtain network device names, use the objdir\device command provided by the Windows 2000 Device Driver Kit.) There should be one link directive for each network interface, and each network interface configured for LLT must be attached to a separate physical network. LLT uses an unregistered Ethernet SAP of 0xCAFE. If the SAP is unacceptable, refer to the llttab.txt online Help for information on how to customize SAP. Note that IP addresses need not be assigned to the network device because LLT does not use IP addresses.

link-lowpri Use this directive in place of link for public network interfaces. This directive prevents VCS communication on the public network until the network is the last link, and reduces the rate of heartbeat broadcasts. Note that LLT distributes network traffic evenly across all available network connections and broadcasts heartbeats to monitor each network connection.

set-cluster Assigns a unique cluster number. Use this directive when more than one cluster is configured on the same physical network connection. Note that LLT uses a default cluster number of zero.

set-node Assigns the node ID. This number must be unique for each node in the cluster, and must be between 0-31.

Note: LLT fails to operate if nodes share the same ID.

start This directive must always appear last.
Group Membership Atomic Broadcast (GAB)

During installation, a gabtab.txt configuration file is automatically created and placed in the following directory on each system in the cluster:

\textit{Drive:}\textbackslash Program Files\textbackslash VERITAS\comms\gab

Verifying LLT, GAB, and cluster operation

Before verifying LLT, GAB, or cluster operation, you must log on to any node in the cluster using an account with administrator privileges.

Verifying LLT

Use the \texttt{lltstat} command to verify the links are active for LLT. This command returns information about the LLT links for the node on which it is typed.

In the following example, \texttt{lltstat -n} is typed on System 0 and System 1 in a private network.

\textbf{System 0}

\begin{verbatim}
Drive:\> lltstat -n

LLT node information:

<table>
<thead>
<tr>
<th>Node</th>
<th>Node Name</th>
<th>State</th>
<th>Links</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>HOUWIN201</td>
<td>OPEN</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>HOUWIN202</td>
<td>OPEN</td>
<td>2</td>
</tr>
</tbody>
</table>
\end{verbatim}

\textbf{System 1}

\begin{verbatim}
Drive:\> lltstat -n

LLT node information:

<table>
<thead>
<tr>
<th>Node</th>
<th>Node Name</th>
<th>State</th>
<th>Links</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>HOUWIN201</td>
<td>OPEN</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>*1 HOUWIN202</td>
<td>OPEN</td>
<td>2</td>
</tr>
</tbody>
</table>
\end{verbatim}

Note that each node has two links and each node is in the \textit{OPEN} state. The asterisk (*) denotes the node on which the command is typed.
If the output of `lltstat -n` does not show each node in the cluster, or does not show two links for each node, type `lltstat -nvv |` to view additional information about LLT. In the following example, `lltstat -nvv | more` is typed on System 0 in a private network. Note that each node should be OPEN, each link should be UP, and each address should be correct.

```
Node  Node Name  State  Link  Status  Address
*0    HOUWIN201 OPEN Adapter0 UP  00:03:47:0D:A8:74
      Adapter1 UP  00:03:47:0D:A8:75
1     HOUWIN202 OPEN Adapter0 UP  00:03:47:0D:A4:46
      Adapter1 UP  00:03:47:0D:A4:47
```

To obtain information about the ports open for LLT, type `lltstat -p` on any node. In the following example, `lltstat -p` is typed on System 0 in a private network.

```
Port  Usage  Cookie
```
Troubleshooting VCS startup

Setting the checksum option
Do not use these options unless you are asked to do so by a qualified Technical Support representative.

\texttt{lltconfig -K 0 | 1 | 2}

- **0** - Disable checksums.
- **1** - Calculate checksum value for header.
  When set to 1, LLT checksums each packet it sends to peer to guard against packet corruption on the wire. LLT also offloads checksum calculation to the hardware if the underlying NIC supports it.
  In case checksum verification fails on the receiver, LLT drops that packet, causing the sender to retransmit it.
- **2** - Checksum calculated for header and message.
  When set to 2, LLT also checksums the whole data buffer submitted by the client to be verified by the peer before delivering it to peer-client. In case the checksum verification fails on the receiver, LLT panics the machine. This is purposefully done to help in analysis of memory corruption from a crash dump.

You can also set the checksum by adding the following information to the \texttt{lltconfig} file

\texttt{set-checksum 0 | 1 | 2}

Verifying GAB
To verify GAB operation, type the following command as Administrator on each node:

\texttt{Drive:\> gabconfig -a}

If GAB is operating, the following GAB port membership information is returned:

\begin{verbatim}
GAB Port Memberships
===================================
Port a gen a36e0003 membership 01
Port h gen fd570002 membership 01
\end{verbatim}
Port a indicates GAB is communicating, gen a36e0003 is a random generation number, and membership 01 indicates nodes 0 and 1 are connected.

If GAB is not operating, no GAB port membership information is returned:

GAB Port Memberships
===================================

If only one network is connected, the following GAB port membership information is returned:

GAB Port Memberships
===================================

Port a gen a36e0003 membership 01
Port h gen fd570002 membership 01

Verifying HAD

To verify HAD operation, type the following command as Administrator on each node:

Drive:\> gabcconfig -a

If HAD is operating, the following port membership information is returned:

GAB Port Memberships
===================================

Port h indicates HAD is started, gen fd570002 is a random generation number, and membership 01 indicates nodes 0 and 1 are both running VCS.

If HAD is not operating, no port membership information is returned.

GAB Port Memberships
===================================

See “VCS seeding” on page 687 for instructions on how to seed the cluster.

If HAD is running on only one node, the following port membership information is returned:
Troubleshooting and recovery for VCS

Troubleshooting VCS startup

GAB Port Memberships

<table>
<thead>
<tr>
<th>Port</th>
<th>a</th>
<th>gen</th>
<th>a36e0003</th>
<th>membership 01</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>h</td>
<td>gen</td>
<td>fd570002</td>
<td>membership 0</td>
</tr>
<tr>
<td>Port</td>
<td>h</td>
<td>gen</td>
<td>fd51002</td>
<td>visible ;1</td>
</tr>
</tbody>
</table>

This information indicates HAD is running on node 1, but only GAB is running on node 0. Check the Application Event Log on node 0 for more information.

Verifying the cluster

To verify cluster operation, type the following command as Administrator on any node:

```
Drive:\> hasys -display
```

<table>

</table>
Note the value for the attribute ConfigFile is an empty file created by default to enable VCS to start. Also note the value of the attribute SysState is RUNNING, which indicates VCS is started. This output indicates VCS was successfully installed on both nodes in the cluster.

VCS startup errors

This section includes error messages associated with starting VCS and provides descriptions of each error and the recommended action.

"VCS:10622 local configuration missing"
"VCS:10623 local configuration invalid"
"VCS:10624 local configuration stale"

The local configuration is invalid.

**Recommended Action:** Start the VCS engine, HAD, on another system that has a valid configuration file. The system with the configuration error "pulls" the valid configuration from the other system.

Another method is to correct the configuration file on the local system and force VCS to reread the configuration file. If the file appears valid, verify that is not an earlier version. It is possible that VCS marked the configuration stale by creating a .stale file because the last VCS shutdown was not graceful. The .stale file is created in the directory %VCS_HOME%/conf/config.

Type the following commands to verify the configuration and force VCS to reread the configuration file:

```
C:\> cd %VCS_HOME%\conf\config
C:\> hacf -verify .
C:\> hasys -force system
```

"VCS:11032 registration failed. Exiting"

GAB was not registered or has become unregistered.

**Recommended Action:** GAB is registered by the gabconfig command in the file %VCS_ROOT%/comms\gab\gabtab.txt. Verify that the file exists and that it contains the command gabconfig -c.

GAB can become unregistered if LLT is set up incorrectly. Verify that the file is correct in %VCS_ROOT%/comms\llt\llttab.txt. If the LLT configuration is incorrect, make the appropriate changes and reboot.

"Waiting for cluster membership."

This indicates that GAB may not be seeded. If this is the case, the command gabconfig -a does not show any members, and the following messages may appear on the console or in the event log.

```
GAB: Port a registration waiting for seed port membership
GAB: Port h registration waiting for seed port membership
```
The following message will also be sent to the engine log:
Did not receive cluster membership, manual intervention may be needed for seeding

Follow the instructions below to seed the cluster:

To seed the cluster

1. Verify the value of gabconfig -c in the file
   %VCS_ROOT%\comms\gab\gabtab.txt is the same for all nodes.

2. Determine how many nodes are operational.

3. For each cluster node, modify gabtab.txt to reflect the required number of members to seed are equal to the number of cluster nodes in operation.

4. Reboot each node, or stop HAD -force on all nodes and restart.
   See “VCS seeding” on page 687 for more information.
Troubleshooting secure clusters

"Error returned from engine: HAD on this node not accepting clients."
This error occurs when an HA command fails because the VCS engine could not initialize its security credentials. When this occurs, the following message is logged to the event log:

"Security ON. Init failed. Clients will be rejected."

Recommended Action:

- Verify the Symantec Product Authentication Service configuration.
  Make sure the cluster was configured to run in secure mode before the SecureClus attribute was set to 1.
  See "Enabling and disabling Symantec Product Authentication Service" on page 443.
- Verify the Veritas Authentication Service is running. Stop and restart the service.
- Restart the VCS engine (HAD) on the node.

"Unable to connect to the VCS engine securely."

Recommended Action:

- Verify the Veritas Authentication Service is running. Stop and restart the service.
- Restart the VCS engine (HAD) on the node.

Troubleshooting service groups

This section cites the most common problems associated with bringing service groups online and taking them offline. Recommended action is also included, where applicable.

System is not in RUNNING state.

**Recommended Action:** Type `hasys -display system` to verify the system is running.

See “System states” on page 740 for more information on system states.

Service group not configured to run on the system.

The SystemList attribute of the group may not contain the name of the system.

**Recommended Action:** Use the output of the command `hagrp -display service_group` to verify the system name.

Service group not configured to autostart.
If the service group is not starting automatically on the system, the group may not be configured to AutoStart, or may not be configured to AutoStart on that particular system.

**Recommended Action:** Use the output of the command `hagrp-display service_group` to verify the values of the AutoStart and AutoStartList attributes.

**Service group is frozen.**

**Recommended Action:** Use the output of the command `hagrp-display service_group` to verify the value of the Frozen and TFrozen attributes. Use the command `hagrp-unfreeze` to unfreeze the group. Note that VCS will not take a frozen service group offline.

**Service group autodisabled.**

When VCS does not know the status of a service group on a particular system, it autodisables the service group on that system. Autodisabling occurs under the following conditions:

- When the VCS engine, HAD, is not running on the system.
- When all resources within the service group are not probed on the system.
- When a particular system is visible through disk heartbeat only. Under these conditions, all service groups that include the system in their SystemList attribute are autodisabled. *This does not apply to systems that are powered off.*

**Recommended Action:** Use the output of the command `hagrp-display service_group` to verify the value of the AutoDisabled attribute.

**Caution:** To bring a group online manually after VCS has autodisabled the group, make sure that the group is not fully or partially active on any system that has the AutoDisabled attribute set to 1 by VCS. Specifically, verify that all resources that may be corrupted by being active on multiple systems are brought down on the designated systems. Then, clear the AutoDisabled attribute for each system:

```
C:\> hagrp -autoenable service_group -sys system
```

**Failover service group is online on another system.**

The group is a failover group and is online or partially online on another system.

**Recommended Action:** Use the output of the command `hagrp-display service_group` to verify the value of the State attribute. Use the command `hagrp-offline` to offline the group on another system.

**Service group is waiting for the resource to be brought online/taken offline.**
**Recommended Action:** Review the IState attribute of all resources in the service group to locate which resource is waiting to go online (or which is waiting to be taken offline). Use the hastatus command to help identify the resource. See the engine and agent logs for information on why the resource is unable to be brought online or be taken offline.

To clear this state, make sure all resources waiting to go online/offline do not bring themselves online/offline. Use the command hagrp -flush to clear the internal state of VCS. You can now bring the service group online or take it offline on another system.

**A critical resource faulted.**

Output of the command hagrp -display service_group indicates that the service group has faulted.

**Recommended Action:** Use the command hares -clear to clear the fault.

**Service group is waiting for a dependency to be met.**

**Recommended Action:** To see which dependencies have not been met, type hagrp -dep service_group to view service group dependencies, or hares -dep resource to view resource dependencies.

**Service group not fully probed.**

This occurs if the agent processes have not monitored each resource in the service group. When the VCS engine, HAD, starts, it immediately “probes” to find the initial state of all of resources. (It cannot probe if the agent is not returning a value.) A service group must be probed on all systems included in the SystemList attribute before VCS attempts to bring the group online as part of AutoStart. This ensures that even if the service group was online prior to VCS being brought up, VCS will not inadvertently bring the service group online on another system.

**Recommended Action:** Use the output of hagrp -display service_group to see the value of the ProbesPending attribute for the system’s service group. (It should be zero.) To determine which resources are not probed, verify the local Probed attribute for each resource on the specified system. Zero means waiting for probe result, 1 means probed, and 2 means VCS not booted. See the engine and agent logs for information.

**ClusterService group configuration**

If you run the hastop -local command on a node that is not defined in the ClusterService group’s SystemList and has other service groups online, VCS takes the service groups offline on the node and the node gets stuck in the LEAVING state.

To prevent this from happening, make sure that the ClusterService group is defined on all nodes in the cluster. In other words, the SystemList attribute of the ClusterService group must contain all nodes in the cluster.
Troubleshooting resources

This section cites the most common problems associated with bringing resources online and taking them offline. Recommended action is also included, where applicable.

Service group brought online due to failover.
VCS attempts to bring resources online that were already online on the failed system, or were in the process of going online. Each parent resource must wait for its child resources to be brought online before starting.

**Recommended Action:** Verify that the child resources are online.

Waiting for service group states.
The state of the service group prevents VCS from bringing the resource online.

**Recommended Action:** See the appendix “Cluster and system states” for more information on states.

Waiting for child resources.
One or more child resources of parent resource are offline.

**Recommended Action:** Bring the child resources online first.

Waiting for parent resources.
One or more parent resources are online.

**Recommended Action:** Take the parent resources offline first.

Waiting for resource to respond.
The resource is waiting to come online or go offline, as indicated. VCS directed the agent to run an online entry point for the resource.

**Recommended Action:** Verify the resource’s IState attribute. See the engine and agent logs for information on why the resource cannot be brought online.

Agent not running.
The resource’s agent process is not running.

**Recommended Action:** Use `hastatus -summary` to see if the agent is listed as faulted. Restart the agent:

```
C:\> haagent -start resource_type -sys system
```

Invalid agent argument list.
The scripts are receiving incorrect arguments.

**Recommended Action:** Verify that the arguments to the scripts are correct.
Use the output of `hares -display resource` to see the value of the ArgListValues attribute. If the ArgList attribute was dynamically changed, stop the agent and restart it.

To stop the agent, type:
Troubleshooting notification

Occasionally you may encounter problems when using VCS notification. This section cites the most common problems and the recommended actions.

Notifier is configured but traps are not seen on SNMP console.

**Recommended Action:** Verify the version of SNMP traps supported by the console: VCS notifier sends SNMP v2.0 traps. If you are using HP OpenView Network Node Manager as the SNMP, verify events for VCS are configured using xnmevents. You may also try restarting the OpenView daemon (ovw) if, after merging VCS events in vcs_trapd, the events are not listed in the OpenView Network Node Manager Event configuration.

By default, notifier assumes the community string is public. If your SNMP console was configured with a different community, reconfigure it according to the notifier configuration.
Troubleshooting Cluster Management Console (Single Cluster Mode) or Web Console

Occasionally you may encounter problems when using Cluster Management Console (Single Cluster Mode) also referred to as Web Console. This section cites the most common problems and the recommended actions.

Unable to log on.

**Recommended Action:** Verify the user name exists and that the password is correct for the user name. Then verify your browser is Java, Javascript, and cookies enabled.

A Java NullPointerException occurs when connecting to a cluster from the Web Console.

**Recommended Action:** Verify the Security settings for the cluster. Make sure the VCS engine (had) and VCS Command Server both run in the same mode. For example, if the cluster is configured to run in secure mode, make sure HAD and VCS Command Server both run in secure mode. See “Enabling and disabling Symantec Product Authentication Service” on page 443.

Unable to view Cluster Manager on a browser using the Virtual IP/port number in URL (http://[virtual_ip:port_number]/vcs).

**Recommended Action:** Verify that the ClusterService service group, which has the IP and VRTSWebApp resources configured on it, is not offline or faulted on any node. If it is, use the command line to bring the group back online on at least one node.

Unable to view Cluster Manager on a browser using the HostName/port_number in URL (http://[host_name:port_number]/vcs).

**Recommended Action:** Verify that the host is running and that the ClusterService group is online on the host. If the host is down, access Cluster Manager (Web Console) using the URL http://virtual_IP:port_number/vcs. The cause of the failover should be apparent on Cluster Manager. Use Cluster Manager to administer nodes that are up and running in cluster.

Unable to bring the VCSweb resource online in the ClusterService group.

You cannot access the Web Console unless the VCSweb resource in the ClusterService group is online. The Web Console runs inside the VERITAS Web server (VRTSweb). VCSweb may fail to come online if the Web server cannot start because of one of the following reasons:
Troubleshooting and recovery for VCS

Troubleshooting Cluster Management Console (Single Cluster Mode) or Web Console

- Web server port unavailable: By default, the Web server binds itself to ports 8181, 8443, and 14300. If these ports are being used by another application, the Web server will fail to start.

  To determine if this is the reason, review the last few lines of the log file. If the output resembles the example below, the Web server port is already taken by another application:

  ```
  5/28/03 8:13:35 PM PDT VRTSWEB INFO V-12-1-1041 Exception encountered
  LifecycleException: Protocol handler initialization failed:
  java.net.BindException: Address already in use: JVM_Bind:8181

  at vrts.tomcat.bootstrap.Main.main(Main.java:243)
  
  Recommended Action: If you cannot make this port available for VRTSweb, refer to “Configuring ports for VRTSweb” on page 800 for instructions on how to change the value of the Web server port.

- Web server IP address unavailable: By default, the Web server binds itself to all IP addresses on the machine for the default ports 8181 and 8443. If you configure a specific IP address for the port, verify this IP address is available on the machine before the Web server starts. The Web server will fail to start if this IP address is not present on the machine.

  If the log output resembles the example below, the IP address is not available:

  ```
  5/28/03 8:20:16 PM PDT VRTSWEB INFO V-12-1-1041 Exception encountered
  LifecycleException: Protocol handler initialization failed:
  java.net.BindException: Cannot assign requested address: JVM_Bind:8181
  at org.apache.coyote.tomcat4.CoyoteConnector.initialize
  (CoyoteConnector.java:1119)
  at org.apache.catalina.startup.Embedded.start(Embedded.java:999)
  at vrts.tomcat.server.VRTSweb.initServer(VRTSweb.java:2567)
  at vrts.tomcat.server.VRTSweb.commandStartServer
  (VRTSweb.java:385)
  at vrts.tomcat.server.command.start.StartCommand.execute
  (StartCommand.java:59)
  at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
  at sun.reflect.NativeMethodAccessorImpl.invoke
  (NativeMethodAccessorImpl.java:39)
  at sun.reflect.DelegatingMethodAccessorImpl.invoke
  (DelegatingMethodAccessorImpl.java:25)
  at java.lang.reflect.Method.invoke(Method.java:324)
  ```
Recommended Action: Make this IP address available on the machine and try to bring the VCSweb resource online again.

After reconfiguring virtual IP address, cannot access the Web Console using the new IP address.

Recommended Action: If ClusterService service group is online, changes in resource attributes do not take effect until you take the service group offline and bring it online. Therefore, you cannot access the Web Console using the new IP address, but you can from the previous address.

To reconfigure the virtual IP address:

1. Take the VCSweb and webip resources offline.
2. Change the address attribute of the webip resource.
3. Bring the VCSweb and webip resources online.

Flashing colors appear on Netscape while switching between Cluster Manager and other open windows.

Recommended Action: If there are flashes of color while viewing Cluster Manager on Netscape Navigator 4.7 or later, it is mostly likely a
color-mapping issue. Set the display to 256 colors or a higher on the host machine where the GUI is being viewed to ensure best color and clarity.

"The object type specified is invalid. It should be one of cluster, group, type, resource, or system."

**Recommended Action:** This error (#W10002) occurs if the page URL points to a VCS object that does not exist or was deleted. If you typed the URL, verify the URL is correct. Names of VCS objects are case-sensitive: the object name in the URL must be entered in the correct case. If you clicked a link and got this error, refresh the page and retry. If you are still unsuccessful, contact Symantec Technical Support.

"The specified group does not exist or has been deleted."

**Recommended Action:** This error (#W10003) indicates the service group whose information you tried to access does not exist, or was deleted. If you typed the URL, verify the URL is correct. If you clicked a link to get information about the service group, verify the service group exists. Refresh the display to get current information.

"The specified system does not exist or has been deleted."

**Recommended Action:** This error (#W10004) indicates the system whose information you tried to access does not exist, or was deleted. If you typed the URL, verify the URL is correct. If you clicked a link to get information about the system, verify the system exists. Refresh the display to get current information.

"The specified resource type does not exist or has been deleted."

**Recommended Action:** This error (#W10005) indicates the resource type whose information you tried to access does not exist, or was deleted. If you typed the URL, verify the URL is correct. If you clicked a link to get information about the resource type, verify the resource type exists. Refresh the display to get current information.

"The specified resource does not exist or has been deleted."

**Recommended Action:** This error (#W10007) indicates the resource whose information you tried to access does not exist, or was deleted. If you typed the URL, verify the URL is correct. If you clicked a link to get information about the resource type, verify the resource exists. Refresh the display to get current information.

"Retrieving data from the VCS engine. Please try after some time."

**Recommended Action:** This error (#R10001) indicates a “snapshot” of the VCS engine, HAD, is being taken. Wait a few moments then retry the operation.

"Could not log on to the VCS engine."
Recommended Action: This error (#R10002) indicates Cluster Manager (Web Console) could not connect to the VCS engine. Wait a few moments then retry the operation.

“Cannot monitor VCS QuickStart.”

Recommended Action: This error (R10005) indicates you tried to connect to a cluster configured by VCS QuickStart. Cluster Manager (Web Console) cannot connect to VCS QuickStart. Use the VCS QuickStart Web graphical user interface instead.

“The user could not be authenticated at this time. This could be because a snapshot of the VCS Server is being taken currently.”

Recommended Action: This error (#H10001) indicates a snapshot of the VCS engine is being taken. Wait a few moments then retry the operation.

“The URL you specified can be accessed only if you are logged on.”

Recommended Action: This error (#G10001) indicates you tried to access a page that requires authentication. Log on to VCS and retry the operation.
Troubleshooting VCS configuration backup and restore

This section cites the problem you may encounter when using the hasnap command to backup and restore VCS configuration files.

Error connecting to remote nodes in the cluster.

The hasnap command is a distributed command in the sense that it tries to backup and restore files from all cluster nodes in a single session. It needs to establish connection with all cluster nodes from the node where the command is executed. The connection may fail for one of the following reasons:

- The hasnap command retrieves the list of cluster nodes from the llthosts configuration file. However, the node names in this file may not always be DNS resolvable, in which case the command cannot establish connection with the remote nodes.
  
  Recommended Action: For each node in the cluster, map the VCS node names to the actual DNS-resolvable names using the hasnap configuration file.

- The hasnap command uses the VCS Command Server Daemon running on the remote nodes to establish connection. The connection fails if the Daemon is not running on the remote node.
  
  Recommended Action: Verify the VCS Command Server Daemon is running on all cluster nodes.

- The remote node might be currently down or unreachable.
  
  Recommended Action: Run the hasnap command again after the bringing the remote node online.
Troubleshooting and recovery for global clusters

This section describes the concept of disaster declaration and provides troubleshooting tips for configurations using global clusters.

Disaster declaration

When a cluster in a global cluster transitions to the FAULTED state because it can no longer be contacted, failover executions depend on whether the cause was due to a split-brain, temporary outage, or a permanent disaster at the remote cluster.

If you choose to take action on the failure of a cluster in a global cluster, VCS prompts you to declare the type of failure.

- Disaster, implying permanent loss of the primary data center
- Outage, implying the primary may return to its current form in some time
- Disconnect, implying a split-brain condition; both clusters are up, but the link between them is broken
- Replica, implying that data on the takeover target has been made consistent from a backup source and that the RVGPrimary can initiate a takeover when the service group is brought online. This option applies to VVR environments only.

You can select the groups to be failed over to the local cluster, in which case VCS brings the selected groups online on a node based on the group’s FailOverPolicy attribute. It also marks the groups as being offline in the other cluster. If you do not select any service groups to fail over, VCS takes no action except implicitly marking the service groups as offline on the downed cluster.
Lost heartbeats and the inquiry mechanism

The loss of internal and all external heartbeats between any two clusters indicates that the remote cluster is faulted, or that all communication links between the two clusters are broken (a wide-area split-brain).

A configuration with more than two clusters must distinguish between the two (Systems A and B) by querying the remaining clusters to confirm the remote cluster to which heartbeats have been lost is truly down. This mechanism is referred to as “Inquiry.” If in a two-cluster configuration a connector loses all heartbeats (internal and external) to the other connector, it must consider the remote cluster faulted. If there are more than two clusters and a connector loses all heartbeats to a second cluster, it queries the remaining connectors regarding their “view” of the cluster in question before declaring it faulted. If the other connectors view the cluster as running (a negative inquiry), the querying connector transitions the cluster to the UNKNOWN state, a process that minimizes false cluster faults. If all connectors report that the cluster is faulted (a positive inquiry), the querying connector also considers it faulted and transitions the remote cluster state to FAULTED.

VCS alerts

VCS alerts are identified by the alert ID, which is comprised of the following elements:

- alert_type—The type of the alert, described in “Types of alerts.”
- cluster—The cluster on which the alert was generated
- system—The system on which this alert was generated
- object—The name of the VCS object for which this alert was generated. This could be a cluster or a service group.

Alerts are generated in the following format:

alert_type-cluster-system-object

For example:

GNOFAILA-Cluster1-oracle_grp

This is an alert of type GNOFAILA generated on cluster Cluster1 for the service group oracle_grp.
Types of alerts
VCS generates the following types of alerts.

- CFAULT—Indicates that a cluster has faulted
- GNOFAILA—Indicates that a global group is unable to fail over within the cluster where it was online. This alert is displayed if the ClusterFailOverPolicy attribute is set to Manual and the wide-area connector (wac) is properly configured and running at the time of the fault.
- GNOFAIL—Indicates that a global group is unable to fail over to any system within the cluster or in a remote cluster. Some reasons why a global group may not be able to fail over to a remote cluster:
  - The ClusterFailOverPolicy is set to either Auto or Connected and VCS is unable to determine a valid remote cluster to which to automatically the group over.
  - The ClusterFailOverPolicy attribute is set to Connected and the cluster in which the group has faulted cannot communicate with one ore more remote clusters in the group's ClusterList.
  - The wide-area connector (wac) is not online or is incorrectly configured in the cluster in which the group has faulted

Managing alerts
Alerts require user intervention. You can respond to an alert in the following ways:

- If the reason for the alert can be ignored, use the Alerts dialog box in the Java or Web consoles or the haalert command to delete the alert. You must provide a comment as to why you are deleting the alert; VCS logs the comment to engine log.
- Take an action on administrative alerts that have actions associated with them. You can do so using the Java or Web consoles.
  See “Actions associated with alerts” on page 713.
- VCS deletes or negates some alerts when a negating event for the alert occurs.
  See “Negating events” on page 713.

An administrative alert will continue to live if none of the above actions are performed and the VCS engine (HAD) is running on at least one node in the cluster. If HAD is not running on any node in the cluster, the administrative alert is lost.
Actions associated with alerts
This section describes the actions you can perform from the Java and the Web consoles on the following types of alerts:

- **CFAULT**—When the alert is presented, clicking Take Action guides you through the process of failing over the global groups that were online in the cluster before the cluster faulted.

- **GNOFAILA**—When the alert is presented, clicking Take Action guides you through the process of failing over the global group to a remote cluster on which the group is configured to run.

- **GNOFAIL**—There are no associated actions provided by the consoles for this alert

Negating events
VCS deletes a CFAULT alert when the faulted cluster goes back to the running state.

VCS deletes the GNOFAILA and GNOFAIL alerts in response to the following events:

- The faulted group’s state changes from FAULTED to ONLINE.

- The group’s fault is cleared.

- The group is deleted from the cluster where alert was generated.
VCS utilities

VCS provides several utilities that address common issues, however, you must use them with extreme caution. For best results, contact Symantec Technical Support prior to using the utilities described below.

The getcomms utility

The getcomms utility collects and saves information related to the private network. The information can be used by Technical Support to debug network-related issues.

To run the getcomms utility

Run getcomms using the Perl executables provided with VCS.

C:\> "VRTS_HOME\VRTSperl\bin\perl.exe" getcomms.pl [-option]

The variable VRTS_HOME represents the Veritas installation directory, typically C:\Program Files\VERITAS. If you chose the default installation paths, use the following command to run getcomms:

C:\> "C:\Program Files\VERITAS\VRTSperl\bin\perl.exe" getcomms.pl [-option]

gecomms options

Use the following options to limit the diagnostic information to specific components.

<table>
<thead>
<tr>
<th>Options</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>-local</td>
<td>Retrieves and dumps information about the local system</td>
</tr>
<tr>
<td>-remote</td>
<td>Retrieves and dumps information about all live systems in the cluster</td>
</tr>
<tr>
<td>-stuck</td>
<td>Prints the message queue</td>
</tr>
<tr>
<td>-d logdir</td>
<td>Dumps information at the directory specified by the variable logdir</td>
</tr>
</tbody>
</table>

Log location

The getcomms utility writes the output to the directory %temp%\commslog.timestamp where %temp% is a system-defined environment variable and timestamp represents the time the log was taken.
The hagetcf utility

The hagetcf utility retrieves and writes detailed diagnostic information about the VCS configuration. The information can be used by Technical Support to debug configuration related issues.

To access hagetcf, type:

```
C:\> hagetcf [-option]
```

Running hagetcf displays output similar to the following example:

```
Veritas Cluster Server(TM) 5.1 for Windows 2003/2008 Diagnostics
Copyright (C) 2008 Symantec Corporation. All rights reserved.
Dumping output to: C:\Program Files\Veritas\Cluster Server\hagetcf\<date_timestamp>
```

Log location

By default, hagetcf writes the output to the directory \%vcs_home%\hagetcf, where \%vcs_home% is the VCS installation directory, typically C:\Program Files\Veritas\Cluster Server.

Options for the hagetcf utility

The hagetcf utility includes various options that you can use to retrieve details about specific components in the configuration.

If you do not specify any options, the hagetcf command retrieves diagnostic information with the following options:

```
-app, -sys, -ha, -log, -lock, -conf, -state, -islog, -trigger
```

The output also includes information about MSDTC and the VCS agent for MSDTC.

If you specify an option, hagetcf dumps the default diagnostic information and information related to the specified options.

*Table 22-3* lists the various options available with the hagetcf command.

---

**Table 22-3**

<table>
<thead>
<tr>
<th>Options</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>-default</strong></td>
<td>Dumps the default VCS logs that include outputs of the following hagetcf command options:</td>
</tr>
<tr>
<td></td>
<td>-app, -sys, -hw, -ha, -log, -lock, -conf, -state, -islog, -trigger</td>
</tr>
<tr>
<td>Note:</td>
<td>The output also includes information about MSDTC and the VCS agent for MSDTC.</td>
</tr>
<tr>
<td><strong>-app</strong></td>
<td>Dumps the application event log.</td>
</tr>
<tr>
<td>Options</td>
<td>Action</td>
</tr>
<tr>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>-sec</td>
<td>Dumps the security event log.</td>
</tr>
<tr>
<td>-sys</td>
<td>Dumps the system event log.</td>
</tr>
<tr>
<td>-hw</td>
<td>Dumps the hardware event log.</td>
</tr>
<tr>
<td></td>
<td>(Applicable for Windows Server 2008 only)</td>
</tr>
<tr>
<td>-allevt</td>
<td>Dumps all event logs.</td>
</tr>
<tr>
<td>-conf</td>
<td>Dumps the VCS config directory.</td>
</tr>
<tr>
<td>-log</td>
<td>Dumps the VCS log directory.</td>
</tr>
<tr>
<td>-ldf</td>
<td>Dumps the VCS ldf directory.</td>
</tr>
<tr>
<td>-lock</td>
<td>Dumps the lock directory.</td>
</tr>
<tr>
<td>-triggers</td>
<td>Dump all files from the VCS triggers directory.</td>
</tr>
<tr>
<td>-alldir</td>
<td>Dumps the config, log, ldf, and lock directories.</td>
</tr>
<tr>
<td>-ha</td>
<td>Dumps the output of the following commands:</td>
</tr>
<tr>
<td></td>
<td>hares -display -all</td>
</tr>
<tr>
<td></td>
<td>hagrp -display -all</td>
</tr>
<tr>
<td></td>
<td>hasys -display</td>
</tr>
<tr>
<td></td>
<td>getcomms.pl</td>
</tr>
<tr>
<td>-state</td>
<td>Dumps the following system state information:</td>
</tr>
<tr>
<td></td>
<td>■ Dr. Watson log</td>
</tr>
<tr>

<td>-msmq</td>
<td>Dumps information about MSMQ.</td>
</tr>
<tr>
<td>-iis</td>
<td>Dumps IIS information.</td>
</tr>
<tr>
<td>-notes</td>
<td>Dumps Notes information.</td>
</tr>
<tr>
<td>-allagents</td>
<td>Dumps information about all VCS application agents. For example, SQL, Exchange, IIS, MSMQ.</td>
</tr>
<tr>
<td>-islog</td>
<td>Dumps installation log.</td>
</tr>
<tr>
<td>-haver</td>
<td>Dumps version information about all VCS binaries.</td>
</tr>
<tr>
<td>-nogetcomms</td>
<td>Excludes the output of the getcomms.pl command.</td>
</tr>
<tr>
<td>-vxlog</td>
<td>Dumps diagnostic information about the following:</td>
</tr>
<tr>
<td></td>
<td>■ Backup Exec</td>
</tr>
<tr>
<td></td>
<td>■ Veritas Enterprise Administrator</td>
</tr>
<tr>
<td>-o &lt;outdir&gt;</td>
<td>Dumps hagetcf output to &lt;outdir&gt;.</td>
</tr>
<tr>
<td>-? or -help</td>
<td>Displays the command’s usage information.</td>
</tr>
</tbody>
</table>
The NICTest utility

The NICTest utility determines whether a NIC maintains its connection status in a system-defined variable. The utility helps configuring NICs under VCS.

Using NICTest

To perform the NIC test

1. At the command prompt, type:
   
   C:\> NICTest adapter_macaddress
   
   The variable adapter_macaddress represents the physical address of the adapter. You can retrieve the MAC address using the `ipconfig -all` command. The utility displays an error message if the entered MAC address is invalid or if it cannot find the specified adapter.
   
   The utility prompts you to ensure that the NIC is connected:
   
   Please ensure that the NIC is connected to the network and press Enter.

2. Press Return. The utility prompts you to disconnect the NIC.

3. Disconnect the NIC and press Return. The system prompts you to connect the NIC.

4. Connect the NIC and press Return.
   
   If the NIC does not maintain its connection status, the following message is displayed:
   
   NIC <adapter_macaddress> does not maintain the connection status.

   If the NIC maintains its connection status, the following message is displayed:
   
   NIC <adapter_macaddress> maintains the connection status.
   
   Please set the UseConnectionStatus attribute for this resource to True.
The VCSRegUtil utility

If an application is run outside of VCS, registry changes are not logged to the shared disk. VCS provides a utility, VCSRegUtil.exe, that marks the system on which registry changes are made outside of the VCS environment.

If a system is marked by the VCSRegUtil utility, the agent detects registry changes when VCS is started. The agent then logs changes to the shared disk. Therefore, you must run the VCSRegUtil.exe utility whenever you run the clustered application outside of VCS. For example, you must use it when issuing the command `hastop -all -force` to take all resources offline and run the application outside the VCS environment. The utility also unmarks a previously marked system. When the resource is brought online on a system marked by this utility, the agent unmarks the system.

**Note:** If a system is marked using VCSRegUtil.exe, and if the attribute `RestoreLocally` is set to 1, the system marking overrides the `RestoreLocally` attribute and registry changes are not applied to the system when it is brought online.

**To mark a system**

At the command prompt, type:

```
C:\> VCSRegUtil /RESOURCE=RegRepResourceName /MARK
```

**To unmark a system**

At the command prompt, type:

```
C:\> VCSRegUtil /RESOURCE=RegRepResourceName /UNMARK
```
The havol utility

The havol utility provides the following options:

- `-getdrive`: Retrieves information about the disk and stores it in a file called DriveInfo.txt in the same path from where you executed the command.

- `-scsitest`: Reserves and releases disks. It helps troubleshoot issues related to SCSI reservation.

**Note:** `-scsitest` option is not supported in an SFW environment.

**Syntax**

```
C:\> havol -scsitest <options>
C:\> havol -getdrive [-details]
```

**Using the `-getdrive` option**

At the command prompt, type:

```
C:\> havol -getdrive
```

For detailed information about the disk, type:

```
C:\> havol -getdrive -details
```

The utility retrieves information about the disk and stores it in a file called DriveInfo.txt in the same path from where you executed the command.

**Sample file contents include:**

```
Detailed Information about Fixed Disks with valid volumes in the system: VCSW2K112J

Harddisk Number = 1
Harddisk Type = Basic Disk
Disk Signature = 130349684
Valid Partitions = 3
Access Test = SUCCESS
Partition Number = 3
Partition Type = IFS Partition
Bootable = NO
Partition Size = 400.06 MB
WINNT style Name = \device\Harddisk1\Partition3
Target Name = \Device\HarddiskVolume6
Device Name = \\?
\Volume{03074b0e-b4d7-11d6-b5a9-00d0b7471a1f}\DriveLetter = Unassigned
DrivePath001 = F:\f1\n
Partition Number = 2
Partition Type = IFS Partition
Bootable = NO
```
Using the -scsitest option

At the command prompt, type:

```
C:\> havol -scsitest [/option]
```

The variable *option* represents additional parameters for the command, listed in "Options for the -scsitest command" on page 722.

**Caution:** Reserving or releasing shared disks may cause the configured service groups to fail over to another system.

**Note:** -scsitest option is not supported in an SFW environment.
Retrieving the disk number
Most scsitest options require the disk number. To list the disk numbers visible from the system, type the following command:

```
C:\> havol -scsitest /L
```

Verify the disk signature to ensure you choose the correct disk number. If the required disk number or signature is not listed, try rescanning the SCSI bus. Type:

```
C:\> havol -scsitest /RESCAN
```

Options for the -scsitest command
Use the following options with the scsitest command to limit the diagnostic information to specific components.

<table>
<thead>
<tr>
<th>Table 22-4</th>
<th>-scsitest command: basic options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Basic Options</strong></td>
<td><strong>Action</strong></td>
</tr>
<tr>
<td>-ADDR:1</td>
<td>Gets the SCSI address of disk number 1.</td>
</tr>
<tr>
<td>-LISTDISKS or -L</td>
<td>Lists all visible disks.</td>
</tr>
<tr>
<td>-REL:1</td>
<td>Releases disk number 1.</td>
</tr>
<tr>
<td>-RES:1</td>
<td>Reserves disk number 1.</td>
</tr>
<tr>
<td>-RESCAN</td>
<td>Rescans the SCSI bus.</td>
</tr>
<tr>
<td>-RESET:1</td>
<td>Resets the disk number 1 (in ioctl mode).</td>
</tr>
<tr>
<td>-SIG:1</td>
<td>Retrieves the signature of disk number 1.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<td>Starts the DiskRes driver.</td>
</tr>
<tr>
<td>-STOPDRV</td>
<td>Stops the DiskRes driver.</td>
</tr>
<tr>
<td>-VER</td>
<td>Retrieves the DiskRes.sys version.</td>
</tr>
</tbody>
</table>
The vmgetdrive utility

Use the VMGetDrive utility to retrieve information about the cluster disk groups and configured volumes.

To retrieve information about the cluster disk groups using the VMGetDrive utility

1  At the command prompt, from the path %VCS_HOME%\bin, type:

   %VCS_HOME%\bin> vmgetdrive

   The system retrieves information about the volume and stores it in a file called VMDriverInfo.txt in the same path from where you executed the command.

2  Open the file VMDriverInfo.txt using a text editor, and get the required information. Sample file contents include:

   There are 1 Imported Cluster Disk Groups

   DiskGroup Name = VCS1
   No of disks in diskgroup 'VCS1' = 2
   Harddisk2
   Harddisk3

   No of volumes in diskgroup 'VCS1' = 2
   Volume Name = Stripe1
   Drive Letter = NONE
   File System = NTFS
   Mount Point = NONE
   Volume Label =
   Volume Type = STRIPED
   Volume Name = Volume1
   Drive Letter = NONE
   File System = NTFS
   Mount Point = NONE
   Volume Label =
   Volume Type = CONCATENATED
The hadhelper utility

The VCS HADHelper utility is used to configure the user account for the VCS Helper service. VCS uses the Helper service account context to perform cluster operations that require administrator privileges.

The VCS Helper service user account requires the following privileges:

- Local Administrator on each cluster node
  It is sufficient if the account is a member of the domain Administrators group and the domain Administrators group is itself a member of the local Administrators group on each node.

- Domain user
  The VCS Helper service user account does not require domain Administrator privileges.

- The “Add workstations to domain” privilege must be enabled in Active Directory. This privilege is granted by default to the Authenticated Users group on the domain controller.

- Act as part of the operating system
- Back up files and directories
- Adjust memory quotas for a process
- Restore files and directories
- Log on as a service

Configuring the VCS HAD Helper service manually

Use the HADHelper command to configure the VCS Helper service manually. If you plan to create a new user account for the VCS Helper service, you must have domain Administrator privileges, or you must belong to the domain Account Operators group.

Command syntax

```
HADHelper /Install /User:<user_name> [/Password:<password>]
HADHelper /Uninstall

HADHelper /Configure /User:<user_name> [/Password:<password>]
HADHelper /ShowConfig
```

- If you do not specify a password for the /Install and /Configure options, the command prompts for a password.
- Specify the `<user_name>` as domain\user or user. If you do not append the domain name, the command assumes the user belongs to the current domain.
Assign the privilege **Add workstation to domain** on the domain controller to the user.

**Command options**

Note that the following command options are case-insensitive.

<table>
<thead>
<tr>
<th>Table 22-6 HadHelper command options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Options</strong></td>
</tr>
</tbody>
</table>
| /Install | Installs the HADHelper service, configures the user for the service, assigns the required local security privileges to the user, and adds the user to the local Administrators group.  
If the service already exists, the option configures the user for the service. |
| /Uninstall | UnInstalls the service, removes the local security privileges for the configured user, and removes the user from local Administrators group.  
**Note:** Stop the service before running the command to uninstall the service. |
| /Configure | Changes the user for the service, assigns the required local security privileges to the user, and adds the user to local Administrators group.  
This option does not check for or add the “Add workstations to domain” privilege to the user account. You must manually assign the privilege to the user on the domain controller.  
This option does not check for group memberships. |
| /ShowConfig | Displays the user name, user SID, and the local security privileges held by the user. |

VCS user privileges—administration matrices

- About administration matrices
- Administration matrices

About administration matrices

In general, users with Guest privileges can execute the following command options: -display, -state, and -value.

Users with privileges for Group Operator and Cluster Operator can execute the following options: -online, -offline, and -switch.

Users with Group Administrator and Cluster Administrator privileges can execute the following options: -add, -delete, and -modify.

See "About the VCS user privilege model" on page 67.
Administration matrices

Review the matrices in the following section to determine which command options can be executed within a specific user role. Checkmarks denote the command and option can be executed. A dash indicates they cannot.

Agent Operations (haagent)

Cluster and system states

- Remote cluster states
- System states
Remote cluster states

In global clusters, the “health” of the remote clusters is monitored and maintained by the wide-area connector process. The connector process uses heartbeats, such as ICMP, to monitor the state of remote clusters. The state is then communicated to HAD, which then uses the information to take appropriate action when required. For example, when a cluster is shut down gracefully, the connector transitions its local cluster state to EXITING and notifies the remote clusters of the new state. When the cluster exits and the remote connectors lose their TCP/IP connection to it, each remote connector transitions their view of the cluster to EXITED.

To enable wide-area network heartbeats, the wide-area connector process must be up and running. For wide-area connectors to connect to remote clusters, at least one heartbeat to the specified cluster must report the state as ALIVE.

There are three heartbeat states for remote clusters: HBUNKNOWN, HBALIVE, and HBDEAD.
Table B-1 on page 739 provides a list of VCS remote cluster states and their descriptions.

See “Examples of system state transitions” on page 743.

<table>
<thead>
<tr>
<th>State</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>INIT</td>
<td>The initial state of the cluster. This is the default state.</td>
</tr>
<tr>
<td>BUILD</td>
<td>The local cluster is receiving the initial snapshot from the remote cluster.</td>
</tr>
<tr>
<td>RUNNING</td>
<td>Indicates the remote cluster is running and connected to the local cluster.</td>
</tr>
<tr>
<td>LOST_HB</td>
<td>The connector process on the local cluster is not receiving heartbeats from the remote cluster.</td>
</tr>
<tr>
<td>LOST_CONN</td>
<td>The connector process on the local cluster has lost the TCP/IP connection to the remote cluster.</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>The connector process on the local cluster determines the remote cluster is down, but another remote cluster sends a response indicating otherwise.</td>
</tr>
<tr>
<td>FAULTED</td>
<td>The remote cluster is down.</td>
</tr>
<tr>
<td>EXITING</td>
<td>The remote cluster is exiting gracefully.</td>
</tr>
<tr>
<td>EXITED</td>
<td>The remote cluster exited gracefully.</td>
</tr>
<tr>
<td>INQUIRY</td>
<td>The connector process on the local cluster is querying other clusters on which heartbeats were lost.</td>
</tr>
<tr>
<td>TRANSITIONING</td>
<td>The connector process on the remote cluster is failing over to another node in the cluster.</td>
</tr>
</tbody>
</table>
Examples of cluster state transitions

- If a remote cluster joins the global cluster configuration, the other clusters in the configuration transition their “view” of the remote cluster to the RUNNING state:
  
  INIT -> BUILD -> RUNNING

- If a cluster loses all heartbeats to a remote cluster in the RUNNING state, inquiries are sent. If all inquiry responses indicate the remote cluster is actually down, the cluster transitions the remote cluster state to FAULTED:
  
  RUNNING -> LOST_HB -> INQUIRY -> FAULTED

- If at least one response does not indicate the cluster is down, the cluster transitions the remote cluster state to UNKNOWN:
  
  RUNNING -> LOST_HB -> INQUIRY -> UNKNOWN

- When the ClusterService service group, which maintains the connector process as highly available, fails over to another system in the cluster, the remote clusters transition their view of that cluster to TRANSITIONING, then back to RUNNING after the failover is successful:
  
  RUNNING -> TRANSITIONING -> BUILD -> RUNNING

- When a remote cluster in a RUNNING state is stopped (by taking the ClusterService service group offline), the remote cluster transitions to EXITED:
  
  RUNNING -> EXITING -> EXITED

System states

Whenever the VCS engine is running on a system, it is in one of the states described in the table below. States indicate a system’s current mode of operation. When the engine is started on a new system, it identifies the other systems available in the cluster and their states of operation. If a cluster system is in the state of RUNNING, the new system retrieves the configuration information from that system. Changes made to the configuration while it is being retrieved are applied to the new system before it enters the RUNNING state. If no other systems are up and in the state of RUNNING or ADMIN_WAIT, and the new system has a configuration that is not invalid, the engine transitions to the state LOCAL_BUILD, and builds the configuration from disk. If the configuration is invalid, the system transitions to the state of STALE_ADMIN_WAIT.

Table B-2 on page 741 provides a list of VCS system states and their descriptions.
See “Examples of system state transitions” on page 743.

Table B-2  VCS system states

<table>
<thead>
<tr>
<th>State</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADMIN_WAIT</td>
<td>The running configuration was lost. A system transitions into this state for the following reasons:</td>
</tr>
<tr>
<td></td>
<td>■ The last system in the RUNNING configuration leaves the cluster before another system takes a snapshot of its configuration and transitions to the RUNNING state.</td>
</tr>
<tr>
<td></td>
<td>■ A system in LOCAL_BUILD state tries to build the configuration from disk and receives an unexpected error from hacf indicating the configuration is invalid.</td>
</tr>
<tr>
<td>CURRENT_DISCOVER_WAIT</td>
<td>The system has joined the cluster and its configuration file is valid. The system is waiting for information from other systems before it determines how to transition to another state.</td>
</tr>
<tr>
<td>CURRENT_PEER_WAIT</td>
<td>The system has a valid configuration file and another system is doing a build from disk (LOCAL_BUILD). When its peer finishes the build, this system transitions to the state REMOTE_BUILD.</td>
</tr>
<tr>
<td>EXITING</td>
<td>The system is leaving the cluster.</td>
</tr>
<tr>
<td>EXITED</td>
<td>The system has left the cluster.</td>
</tr>
<tr>
<td>EXITING_FORCIBLY</td>
<td>An hastop -force command has forced the system to leave the cluster.</td>
</tr>
<tr>
<td>FAULTED</td>
<td>The system has left the cluster unexpectedly.</td>
</tr>
<tr>
<td>INITING</td>
<td>The system has joined the cluster. This is the initial state for all systems.</td>
</tr>
<tr>
<td>LEAVING</td>
<td>The system is leaving the cluster gracefully. When the agents have been stopped, and when the current configuration is written to disk, the system transitions to EXITING.</td>
</tr>
<tr>
<td>LOCAL_BUILD</td>
<td>The system is building the running configuration from the disk configuration.</td>
</tr>
<tr>
<td>REMOTE_BUILD</td>
<td>The system is building a running configuration that it obtained from a peer in a RUNNING state.</td>
</tr>
</tbody>
</table>
### Table B-2  VCS system states

<table>
<thead>
<tr>
<th>State</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNNING</td>
<td>The system is an active member of the cluster.</td>
</tr>
<tr>
<td>STALEASE_ADMIN_WAIT</td>
<td>The system has an invalid configuration and there is no other system in the state of RUNNING from which to retrieve a configuration. If a system with a valid configuration is started, that system enters the LOCALBUILD state. Systems in STALEASE_ADMIN_WAIT transition to STALEASE_PEER_WAIT.</td>
</tr>
<tr>
<td>STALEASE_DISCOVER_WAIT</td>
<td>The system has joined the cluster with an invalid configuration file. It is waiting for information from any of its peers before determining how to transition to another state.</td>
</tr>
<tr>
<td>STALEASE_PEER_WAIT</td>
<td>The system has an invalid configuration file and another system is doing a build from disk (LOCALBUILD). When its peer finishes the build, this system transitions to the state REMOTE_BUILD.</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>The system has not joined the cluster because it does not have a system entry in the configuration.</td>
</tr>
</tbody>
</table>
Examples of system state transitions

- If VCS is started on a system, and if that system is the only one in the cluster with a valid configuration, the system transitions to the RUNNING state:
  INITING -> CURRENT_DISCOVER_WAIT -> LOCAL_BUILD -> RUNNING

- If VCS is started on a system with a valid configuration file, and if at least one other system is already in the RUNNING state, the new system transitions to the RUNNING state:
  INITING -> CURRENT_DISCOVER_WAIT -> REMOTE_BUILD -> RUNNING

- If VCS is started on a system with an invalid configuration file, and if at least one other system is already in the RUNNING state, the new system transitions to the RUNNING state:
  INITING -> STALE_DISCOVER_WAIT -> REMOTE_BUILD -> RUNNING

- If VCS is started on a system with an invalid configuration file, and if all other systems are in STALE_ADMIN_WAIT state, the system transitions to the STALE_ADMIN_WAIT state as shown below. A system stays in this state until another system with a valid configuration file is started.
  INITING -> STALE_DISCOVER_WAIT -> STALE_ADMIN_WAIT

- If VCS is started on a system with a valid configuration file, and if other systems are in the ADMIN_WAIT state, the new system transitions to the ADMIN_WAIT state.
  INITING -> CURRENT_DISCOVER_WAIT -> ADMIN_WAIT

- If VCS is started on a system with an invalid configuration file, and if other systems are in the ADMIN_WAIT state, the new system transitions to the ADMIN_WAIT state.
  INITING -> STALE_DISCOVER_WAIT -> ADMIN_WAIT

- When a system in RUNNING state is stopped with the hastop command, it transitions to the EXITED state as shown below. During the LEAVING state, any online system resources are taken offline. When all of the system's resources are taken offline and the agents are stopped, the system transitions to the EXITED state.
  RUNNING -> LEAVING -> EXITING -> EXITED
Cluster and system states

System states
VCS attributes

- About attributes and their definitions
- Resource attributes
- Resource type attributes
- Service group attributes
- System attributes
- Cluster attributes
- Heartbeat attributes (for global clusters)
About attributes and their definitions

In addition to the attributes listed in this appendix, see the Veritas Cluster Server Agent Developer’s Guide.

- You can modify the values of attributes labelled user-defined from the command line or graphical user interface, or by manually modifying the main.cf configuration file. You can change the default values to better suit your environment and enhance performance. When changing the values of attributes, be aware that VCS attributes interact with each other. After changing the value of an attribute, observe the cluster systems to confirm that unexpected behavior does not impair performance.

- VCS sets the values of attributes that are labeled, “system use only.” These are read-only attributes. They contain important information about the state of the cluster.

- Agents set the values of attributes labeled “agent-defined.” These are read-only attributes.

See “About VCS attributes” on page 57.

Resource attributes

Table C-1 lists resource attributes.

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArgListValues</td>
<td>List of arguments passed to the resource's agent on each system. This attribute is resource- and system-specific, meaning that the list of values passed to the agent depend on which system and resource they are intended.</td>
</tr>
<tr>
<td></td>
<td>Type and dimension: string-vector</td>
</tr>
<tr>
<td></td>
<td>Default: non-applicable.</td>
</tr>
<tr>
<td>AutoStart</td>
<td>Indicates the resource is brought online when the service group is brought online.</td>
</tr>
<tr>
<td></td>
<td>Type and dimension: boolean-scalar</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
</tbody>
</table>
### Table C-1 Resource attributes

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| ComputeStats (user-defined) | Indicates to agent framework whether or not to calculate the resource's monitor statistics.  
- Type and dimension: boolean-scalar  
- Default: 0 |
| ConfidenceLevel (agent-defined) | Indicates the level of confidence in an online resource. Values range from 0–100. Note that some VCS agents may not take advantage of this attribute and may always set it to 0. Set the level to 100 if the attribute is not used.  
- Type and dimension: integer-scalar  
- Default: 0 |
| Critical (user-defined) | Indicates whether a fault of this resource should trigger a failover of the entire group or not. If Critical is 0, the resource fault will not cause group failover.  
- Type and dimension: boolean-scalar  
- Default: 1 |
| Enabled (user-defined) | Indicates agents monitor the resource.  
If a resource is created dynamically while VCS is running, you must enable the resource before VCS monitors it. For more information on how to add or enable resources, see the chapters on administering VCS from the command line and graphical user interfaces.  
When Enabled is set to 0, it implies a disabled resource.  
- Type and dimension: boolean-scalar  
- Default: If you specify the resource in main.cf prior to starting VCS, the default value for this attribute is 1, otherwise it is 0. |
[Table C-1 Resource attributes]

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| Flags (system use only) | Provides additional information for the state of a resource. Primarily this attribute raises flags pertaining to the resource. Values:  
  NORMAL—Standard working order.  
  RESTARTING —The resource faulted and that the agent is attempting to restart the resource on the same system.  
  STATE UNKNOWN—The latest monitor call by the agent could not determine if the resource was online or offline.  
  MONITOR TIMEDOUT —The latest monitor call by the agent was terminated because it exceeded the maximum time specified by the static attribute MonitorTimeout.  
  UNABLE TO OFFLINE—The agent attempted to offline the resource but the resource did not go offline. This flag is also set when a resource faults and the clean function completes successfully, but the subsequent monitor hangs or is unable to determine resource status.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable. |
| Group (system use only) | String name of the service group to which the resource belongs.  
  ■ Type and dimension: string-scalar  
  ■ Default: Not applicable. |
Table C-1  Resource attributes

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| IState (system use only) | The internal state of a resource. In addition to the State attribute, this attribute shows to which state the resource is transitioning. Values:  
  - NOT WAITING—Resource is not in transition.  
  - WAITING TO GO ONLINE—Agent notified to bring the resource online but procedure not yet complete.  
  - WAITING FOR CHILDREN ONLINE—Resource to be brought online, but resource depends on at least one offline resource. Resource transitions to WAITING TO GO ONLINE when all children are online.  
  - WAITING TO GO OFFLINE—Agent notified to take the resource offline but procedure not yet complete.  
  - WAITING TO GO OFFLINE (propagate)—Same as above, but when completed the resource’s children will also be offline.  
  - WAITING TO GO ONLINE (reverse)—Resource waiting to be brought online, but when it is online it attempts to go offline. Typically this is the result of issuing an offline command while resource was waiting to go online.  
  - WAITING TO GO OFFLINE (reverse/propagate)—Same as above, but resource propagates the offline operation.  
  **Note:** Although this attribute accepts integer types, the command line indicates the text representations.  
  - Type and dimension: integer-scalar  
  - Default: 1  
  - NOT WAITING |
| LastOnline (system use only) | Indicates the system name on which the resource was last online. This attribute is set by VCS.  
  - Type and dimension: string-scalar  
  - Default: Not applicable |
| MonitorOnly (system use only) | Indicates if the resource can be brought online or taken offline. If set to 0, resource can be brought online or taken offline. If set to 1, resource can only be monitored.  
  **Note:** This attribute can only be modified by the command hagrp-freeze.  
  - Type and dimension: boolean-scalar  
  - Default: 0 |
### Resource attributes

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| MonitorTimeStats    | Valid keys are Average and TS. Average is the average time taken by the monitor function over the last Frequency number of monitor cycles. TS is the timestamp indicating when the engine updated the resource's Average value.  
  - **Type and dimension:** string-association  
  - **Default:** Average = 0  
  
| Name                | Contains the actual name of the resource.  
  - **Type and dimension:** string-scalar  
  - **Default:** Not applicable.  
| Path                | Set to 1 to identify a resource as a member of a path in the dependency tree to be taken offline on a specific system after a resource faults.  
  - **Type and dimension:** boolean-scalar  
  - **Default:** 0  
| Probed              | Indicates whether the state of the resource has been determined by the agent by running the monitor function.  
  - **Type and dimension:** boolean-scalar  
  - **Default:** 0  
| ResourceInfo        | This attribute has three predefined keys:  
  - **State:** values are Valid, Invalid, or Stale  
  - **Msg:** output of the info function captured on stdout by the agent framework  
  - **TS:** timestamp indicating when the ResourceInfo attribute was updated by the agent framework  
  - **Type and dimension:** string-association  
  - **Default:**  
    - State = Valid  
    - Msg = ""  
    - TS = ""  
|
### Table C-1 Resource attributes

<table>
<thead>
<tr>
<th>Resource Attributes</th>
<th>Description</th>

</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 60 seconds</td>
</tr>
</tbody>
</table>

**Note:** This attribute can be overridden.
<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| CleanRetryLimit (user-defined)            | Number of times to retry the clean function before moving a resource to ADMIN_WAIT state. If set to 0, clean is re-tried indefinitely.  
  The valid values of this attribute are in the range of 0-1024.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 0                         |
| CleanTimeout (user-defined)               | Maximum time (in seconds) within which the clean function must complete or else be terminated.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 60 seconds                 |
| CloseTimeout (user-defined)               | Maximum time (in seconds) within which the close function must complete or else be terminated.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 60 seconds                 |
| ConfInterval (user-defined)               | When a resource has remained online for the specified time (in seconds), previous faults and restart attempts are ignored by the agent. (See ToleranceLimit and RestartLimit attributes for details.)  
  ■ Type and dimension: integer-scalar  
  ■ Default: 600 seconds                |
| EPClass                                   | Enables you to control the scheduling class for the agent functions (entry points) other than the online entry point whether the entry point is in C or scripts.  
  The following values are valid for this attribute:  
  ■ RT (Real Time)  
  ■ TS (Time Sharing)  
  ■ -1—indicates that VCS does not use this attribute to control the scheduling class of entry points.  
  Use only one of the following sets of attributes to configure scheduling class and priority for VCS:  
  ■ AgentClass, AgentPriority, ScriptClass, and ScriptPriority  
  Or  
  ■ OnlineClass, OnlinePriority, EPClass, and EPPriority  
  ■ Type and dimension: string-scalar  
  ■ Default: -1 |
Enables you to control the scheduling priority for the agent functions (entry points) other than the online entry point. The attribute controls the agent function priority whether the entry point is in C or scripts.

The following values are valid for this attribute:

- 0—indicates the default priority value for the configured scheduling class as given by the EPClass attribute for the operating system.
- Greater than 0—indicates a value greater than the default priority for the operating system.
- Symantec recommends a value of greater than 0 for this attribute. A system that has a higher load requires a greater value.
- -1—indicates that VCS does not use this attribute to control the scheduling priority of entry points.

For example:

- (Solaris) If the EPClass attribute is set to TS, and the value of the EPPriority attribute is set to 0, then the base priority for entry points is set to 59, as that is the default value set by the operating system.
- (Solaris) If the EPClass attribute is set to TS, and the value of the EPPriority attribute is set to -20, then the scheduling priority of the entry point would be 39 (59 base value and -20 configured value)
- (Solaris) If the EPClass attribute is set to RT, and the value of the EPPriority attribute is set to 0, then the base priority for entry points is set to 100 by the operating system.

Use only one of the following sets of attributes to configure scheduling class and priority for VCS:

- AgentClass, AgentPriority, ScriptClass, and ScriptPriority
- OnlineClass, OnlinePriority, EPClass, and EPPriority

<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPPriority</td>
<td>Enables you to control the scheduling priority for the agent functions (entry points) other than the online entry point. The attribute controls the agent function priority whether the entry point is in C or scripts.</td>
</tr>
</tbody>
</table>

For example:

- (Solaris) If the EPClass attribute is set to TS, and the value of the EPPriority attribute is set to 0, then the base priority for entry points is set to 59, as that is the default value set by the operating system.
- (Solaris) If the EPClass attribute is set to TS, and the value of the EPPriority attribute is set to -20, then the scheduling priority of the entry point would be 39 (59 base value and -20 configured value)
- (Solaris) If the EPClass attribute is set to RT, and the value of the EPPriority attribute is set to 0, then the base priority for entry points is set to 100 by the operating system.

Use only one of the following sets of attributes to configure scheduling class and priority for VCS:

- AgentClass, AgentPriority, ScriptClass, and ScriptPriority
- OnlineClass, OnlinePriority, EPClass, and EPPriority

Type and dimension: string-scalar

Default: -1
### Table C-2 Resource type attributes

<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ExternalStateChange</strong>&lt;br&gt;(user-defined)&lt;br&gt;<strong>Note:</strong> This attribute can be overridden.</td>
<td>Defines how VCS handles service group state when resources are intentionally brought online or taken offline outside of VCS control. The attribute can take the following values:&lt;br&gt;- <strong>OnlineGroup:</strong> If the configured application is started outside of VCS control, VCS brings the corresponding service group online.&lt;br&gt;- <strong>OfflineGroup:</strong> If the configured application is stopped outside of VCS control, VCS takes the corresponding service group offline.&lt;br&gt;- <strong>OfflineHold:</strong> If a configured application is stopped outside of VCS control, VCS sets the state of the corresponding VCS resource as offline. VCS does not take any parent resources or the service group offline. OfflineHold and OfflineGroup are mutually exclusive.</td>
</tr>
<tr>
<td><strong>FaultOnMonitor</strong>&lt;br&gt;Timeouts&lt;br&gt;(user-defined)&lt;br&gt;<strong>Note:</strong> This attribute can be overridden.</td>
<td>When a monitor times out as many times as the value specified, the corresponding resource is brought down by calling the clean function. The resource is then marked FAULTED, or it is restarted, depending on the value set in the RestartLimit attribute. When FaultOnMonitorTimeouts is set to 0, monitor failures are not considered indicative of a resource fault. A low value may lead to spurious resource faults, especially on heavily loaded systems.&lt;br&gt;- Type and dimension: integer-scalar&lt;br&gt;- Default: 4</td>
</tr>
<tr>
<td><strong>FaultPropagation</strong>&lt;br&gt;(user-defined)&lt;br&gt;<strong>Note:</strong> This attribute can be overridden.</td>
<td>Specifies if VCS should propagate the fault up to parent resources and take the entire service group offline when a resource faults. The value 1 indicates that when a resource faults, VCS fails over the service group, if the group's AutoFailOver attribute is set to 1. If the value 0 indicates that when a resource faults, VCS does not take other resources offline, regardless of the value of the Critical attribute. The service group does not fail over on resource fault.&lt;br&gt;- Type and dimension: boolean-scalar&lt;br&gt;- Default: 1</td>
</tr>
</tbody>
</table>
### VCS attributes

#### Resource type attributes

<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FireDrill (user-defined)</td>
<td>Specifies whether or not fire drill is enabled for resource type. If set to 1, fire drill is enabled. If set to 0, it is disabled.</td>
</tr>
<tr>
<td></td>
<td>- Type and dimension: boolean-scalar</td>
</tr>
<tr>
<td></td>
<td>- Default: 0</td>
</tr>
<tr>
<td>InfoInterval (user-defined)</td>
<td>Duration (in seconds) after which the info function is invoked by the agent framework for ONLINE resources of the particular resource type. If set to 0, the agent framework does not periodically invoke the info function. To manually invoke the info function, use the command <code>hares -refreshinfo</code>. If the value you designate is 30, for example, the function is invoked every 30 seconds for all ONLINE resources of the particular resource type.</td>
</tr>
<tr>
<td></td>
<td>- Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>- Default: 0</td>
</tr>
<tr>
<td>IntentionalOffline (user-defined)</td>
<td>Defines how VCS reacts when a configured application is intentionally stopped outside of VCS control. Add this attribute for agents that support detection of an intentional offline outside of VCS control. Note that the intentional offline feature is available for agents registered as V51 or later. The value 0 instructs the agent to register a fault and initiate the failover of a service group when the supported resource is taken offline outside of VCS control. The value 1 instructs VCS to take the resource offline when the corresponding application is stopped outside of VCS control.</td>
</tr>
<tr>
<td></td>
<td>- Type and dimension: boolean-scalar</td>
</tr>
<tr>
<td></td>
<td>- Default: 0</td>
</tr>
<tr>
<td>InfoTimeout (user-defined)</td>
<td>Timeout value for info function. If function does not complete by the designated time, the agent framework cancels the function's thread.</td>
</tr>
<tr>
<td></td>
<td>- Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>- Default: 30 seconds</td>
</tr>
</tbody>
</table>
### LogDbg (user-defined)

Indicates the debug severities enabled for the resource type or agent framework. Debug severities used by the agent functions are in the range of DBG_1–DBG_21. The debug messages from the agent framework are logged with the severities DBG_AGINFO, DBG_AGDEBUG and DBG_AGTRACE, representing the least to most verbose.

- **Type and dimension:** string-keylist
- **Default:** {} (none)

### LogFileSize (user-defined)

Specifies the size (in bytes) of the agent log file. Minimum value is 64 KB. Maximum value is 134217728 bytes (128MB).

- **Type and dimension:** integer-scalar
- **Default:** 33554432 (32MB)

### MonitorInterval (user-defined)

Note: This attribute can be overridden.

Duration (in seconds) between two consecutive monitor calls for an ONLINE or transitioning resource.

A low value may impact performance if many resources of the same type exist. A high value may delay detection of a faulted resource.

**Note:** The value of this attribute for the MultiNICB type must be less than its value for the IPMultiNICB type. See the *Veritas Cluster Server Bundled Agents Reference Guide* for more information.

- **Type and dimension:** integer-scalar
- **Default:** 60 seconds

---

**Table C-2**  
Resource type attributes

<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| LogDbg (user-defined)    | Indicates the debug severities enabled for the resource type or agent framework. Debug severities used by the agent functions are in the range of DBG_1–DBG_21. - **Type and dimension:** integer-scalar  
- **Default:** 33554432 (32MB) |
| MonitorInterval (user-defined) | Duration (in seconds) between two consecutive monitor calls for an ONLINE or transitioning resource.  
A low value may impact performance if many resources of the same type exist. A high value may delay detection of a faulted resource.  
**Note:** The value of this attribute for the MultiNICB type must be less than its value for the IPMultiNICB type. See the *Veritas Cluster Server Bundled Agents Reference Guide* for more information.  
- **Type and dimension:** integer-scalar  
- **Default:** 60 seconds |
### MonitorStatsParam (user-defined)

Stores the required parameter values for calculating monitor time statistics.

**static str MonitorStatsParam = {Frequency = 10, ExpectedValue = 3000, ValueThreshold = 100, AvgThreshold = 40}**

- **Frequency**: The number of monitor cycles after which the average monitor cycle time should be computed and sent to the engine. If configured, the value for this attribute must be between 1 and 30. The value 0 indicates that the monitor cycle time should not be computed. Default=0.
- **ExpectedValue**: The expected monitor time in milliseconds for all resources of this type. Default=100.
- **ValueThreshold**: The acceptable percentage difference between the expected monitor cycle time (ExpectedValue) and the actual monitor cycle time. Default=100.
- **AvgThreshold**: The acceptable percentage difference between the benchmark average and the moving average of monitor cycle times. Default=40.

- Type and dimension: integer-association
- Default: Different value for each parameter

### MonitorTimeout (user-defined)

Maximum time (in seconds) within which the monitor function must complete or else be terminated.

- Type and dimension: integer-scalar
- Default: 60 seconds

**Note**: This attribute can be overridden.

### NumThreads (user-defined)

Number of threads used within the agent process for managing resources. This number does not include threads used for other internal purposes.

If the number of resources being managed by the agent is less than or equal to the NumThreads value, only that many number of threads are created in the agent. Addition of more resources does not create more service threads. Similarly deletion of resources causes service threads to exit. Thus, setting NumThreads to 1 forces the agent to just use 1 service thread no matter what the resource count is. The agent framework limits the value of this attribute to 30.

- Type and dimension: integer-scalar
- Default: 10

</table>
| OnlinePriority          | Enables you to control the scheduling priority for the online agent function (entry point). This attribute controls the priority whether the entry point is in C or scripts.  

The following values are valid for this attribute:

- 0—indicates the default priority value for the configured scheduling class as given by the OnlineClass for the operating system.  
Symantec recommends that you set the value of the OnlinePriority attribute to 0.
- Greater than 0—indicates a value greater than the default priority for the operating system.
- -1—indicates that VCS does not use this attribute to control the scheduling priority of entry points.

For example:

- (Solaris) If the OnlineClass attribute is set to TS, and the value of the OnlinePriority attribute is set to 0, then the base priority for entry points is set to 59, as that is the default value set by the operating system.
- (Solaris) If the OnlineClass attribute is set to TS, and the value of the OnlinePriority attribute is set to -20, then the scheduling priority of the entry point would be 39 (59 base value and -20 configured value).
- (Solaris) If the OnlineClass attribute is set to RT, and the value of the OnlinePriority attribute is set to 0, then the base priority for entry points is set to 100 by the operating system.

Use only one of the following sets of attributes to configure scheduling class and priority for VCS:

- AgentClass, AgentPriority, ScriptClass, and ScriptPriority
- OnlineClass, OnlinePriority, EPClass, and EPPriority

| OnlineRetryLimit | Number of times to retry the online operation if the attempt to online a resource is unsuccessful. This parameter is meaningful only if the clean operation is implemented.  

| Note: This attribute can be overridden. |

- Type and dimension: integer-scalar
- Default: 0
### Resource type attributes

<table>
<thead>
<tr>
<th>Resource type attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| OnlineTimeout (user-defined) | Maximum time (in seconds) within which the online function must complete or else be terminated.  
- Type and dimension: integer-scalar  
- Default: 300 seconds  

**Note:** This attribute can be overridden. |
| OnlineWaitLimit (user-defined) | Number of monitor intervals to wait for the resource to come online after completing the online procedure. Increase the value of this attribute if the resource is likely to take a longer time to come online.  
- Type and dimension: integer-scalar  
- Default: 2  

**Note:** This attribute can be overridden. |
| OpenTimeout (user-defined) | Maximum time (in seconds) within which the open function must complete or else be terminated.  
- Type and dimension: integer-scalar  
- Default: 60 seconds  

**Note:** This attribute can be overridden. |
| Operations (user-defined) | Indicates valid operations for resources of the resource type. Values are OnOnly (can online only), OnOff (can online and offline), None (cannot online or offline).  
- Type and dimension: string-scalar  
- Default: OnOff  

**Note:** This attribute can be overridden. |
| ProcScanInterval | This attribute is obsolete, do not use. |
| RestartLimit (user-defined) | Number of times to retry bringing a resource online when it is taken offline unexpectedly and before VCS declares it FAULTED.  
- Type and dimension: integer-scalar  
- Default: 0  

**Note:** This attribute can be overridden. |
| ScriptClass (user-defined) | Indicates the scheduling class of the script processes (for example, online) created by the agent.  
Use only one of the following sets of attributes to configure scheduling class and priority for VCS:  
- AgentClass, AgentPriority, ScriptClass, and ScriptPriority  
- OnlineClass, OnlinePriority, EPCClass, and EPPriority  
- Type and dimension: string-scalar  
- Default: TS  

**Note:** This attribute can be overridden. |
### Table C-2: Resource type attributes

<table>
<thead>
<tr>
<th>Resource type attributes</th>

<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** This attribute can be overridden.

## Service group attributes

*Table C-3* lists the service group attributes.

### Table C-3 Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| ActiveCount (system use only) | Number of resources in a service group that are active (online or waiting to go online). When the number drops to zero, the service group is considered offline.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable. |
| AdministratorGroups (user-defined) | List of operating system user account groups that have administrative privileges on the service group.  
  This attribute applies to clusters running in secure mode.  
  - Type and dimension: string-keylist  
  - Default: {} (none) |
| Administrators (user-defined) | List of VCS users with privileges to administer the group.  
  **Note:** A Group Administrator can perform all operations related to a specific service group, but cannot perform generic cluster operations.  
  See “About the VCS user privilege model” on page 67.  
  - Type and dimension: string-keylist  
  - Default: {} (none) |
| Authority (user-defined) | Indicates whether or not the local cluster is allowed to bring the service group online. If set to 0, it is not, if set to 1, it is. Only one cluster can have this attribute set to 1 for a specific global group.  
  See “Serialization–The Authority attribute” on page 575.  
  - Type and dimension: integer-scalar  
  - Default: 0 |
765

VCS attributes

Service group attributes

Table C-3  Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| AutoDisabled (system use only) | Indicates that VCS does not know the status of a service group (or specified system for parallel service groups). This can occur because the group is not probed (on specified system for parallel groups) in the SystemList attribute. Or the VCS engine is not running on a node designated in the SystemList attribute, but the node is visible. When VCS does not know the status of a service group on a node but you want VCS to consider the service group enabled, perform this command to change the AutoDisabled value to 0.

hagrp -autoenable grp -sys sys1

This command instructs VCS that even though VCS has marked the service group auto-disabled, you are sure that the service group is not online on sys1. For failover service groups, this is important because the service groups now can be brought online on remaining nodes.

- Type and dimension: boolean-scalar
- Default: 0 |
| AutoFailOver (user-defined) | Indicates whether VCS initiates an automatic failover if the service group faults. The attribute can take the following values:

- 0—VCS does not fail over the service group.
- 1—VCS automatically fails over the service group if a suitable node exists for failover.

See “Controlling failover on service group or system faults” on page 477.

- Type and dimension: boolean-scalar
- Default: 1 (enabled) |
| AutoRestart (user-defined) | Restarts a service group after a faulted persistent resource becomes online. See “About service group dependencies” on page 518.

**Note:** This attribute applies only to service groups containing persistent resources.

- Type and dimension: boolean-scalar
- Default: 1 (enabled) |
Table C-3  Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| AutoStart (user-defined) | Designates whether a service group is automatically started when VCS is started.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 1 (enabled) |
| AutoStartIfPartial (user-defined) | Indicates whether to initiate bringing a service group online if the group is probed and discovered to be in a PARTIAL state when VCS is started.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 1 (enabled) |
| AutoStartList (user-defined) | List of systems on which, under specific conditions, the service group will be started with VCS (usually at system boot). For example, if a system is a member of a failover service group's AutoStartList attribute, and if the service group is not already running on another system in the cluster, the group is brought online when the system is started.  
  VCS uses the AutoStartPolicy attribute to determine the system on which to bring the service group online.  
  **Note:** For the service group to start, AutoStart must be enabled and Frozen must be 0. Also, beginning with 1.3.0, you must define the SystemList attribute prior to setting this attribute.  
  ■ Type and dimension: string-keylist  
  ■ Default: [] (none) |
| AutoStartPolicy (user-defined) | Sets the policy VCS uses to determine on which system to bring a service group online if multiple systems are available.  
  This attribute has three options:  
  Order (default)—Systems are chosen in the order in which they are defined in the AutoStartList attribute.  
  Load—Systems are chosen in the order of their capacity, as designated in the AvailableCapacity system attribute. System with the highest capacity is chosen first.  
  Priority—Systems are chosen in the order of their priority in the SystemList attribute. Systems with the lowest priority is chosen first.  
  ■ Type and dimension: string-scalar  
  ■ Default: Order |
ClusterFailOverPolicy (user-defined)

Determines how a global service group behaves when a cluster faults or when a global group faults. The attribute can take the following values:

- **Manual**—The group does not fail over to another cluster automatically.
- **Auto**—The group fails over to another cluster automatically if it is unable to fail over within the local cluster, or if the entire cluster faults.
- **Connected**—The group fails over automatically to another cluster only if it is unable to fail over within the local cluster.

- **Type and dimension:** string-scalar
- **Default:** Manual

ClusterList (user-defined)

Specifies the list of clusters on which the service group is configured to run.

- **Type and dimension:** integer-association
- **Default:** {} (none)

CurrentCount (system use only)

Number of systems on which the service group is active.

- **Type and dimension:** integer-scalar
- **Default:** Not applicable.

DeferAutoStart (system use only)

Indicates whether HAD defers the auto-start of a global group in local cluster in case the global cluster is not fully connected.

- **Type and dimension:** boolean-scalar
- **Default:** Not applicable

Enabled (user-defined)

Indicates if a service group can be failed over or brought online.

The attribute can have global or local scope. If you define local (system-specific) scope for this attribute, VCS prevents the service group from coming online on specified systems that have a value of 0 for the attribute. You can use this attribute to prevent failovers on a system when performing maintenance on the system.

- **Type and dimension:** boolean-scalar
- **Default:** 1 (enabled)

Evacuate (user-defined)

Indicates if VCS initiates an automatic failover when user issues `hastop -local-evacuate`.

- **Type and dimension:** boolean-scalar
- **Default:** 1

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| ClusterFailOverPolicy (user-defined) | Determines how a global service group behaves when a cluster faults or when a global group faults. The attribute can take the following values:  
- **Manual**—The group does not fail over to another cluster automatically.  
- **Auto**—The group fails over to another cluster automatically if it is unable to fail over within the local cluster, or if the entire cluster faults.  
- **Connected**—The group fails over automatically to another cluster only if it is unable to fail over within the local cluster.  
  - **Type and dimension:** string-scalar  
  - **Default:** Manual |
| ClusterList (user-defined) | Specifies the list of clusters on which the service group is configured to run.  
  - **Type and dimension:** integer-association  
  - **Default:** {} (none) |
| CurrentCount (system use only) | Number of systems on which the service group is active.  
  - **Type and dimension:** integer-scalar  
  - **Default:** Not applicable. |
| DeferAutoStart (system use only) | Indicates whether HAD defers the auto-start of a global group in local cluster in case the global cluster is not fully connected.  
  - **Type and dimension:** boolean-scalar  
  - **Default:** Not applicable |
| Enabled (user-defined) | Indicates if a service group can be failed over or brought online.  
  The attribute can have global or local scope. If you define local (system-specific) scope for this attribute, VCS prevents the service group from coming online on specified systems that have a value of 0 for the attribute. You can use this attribute to prevent failovers on a system when performing maintenance on the system.  
  - **Type and dimension:** boolean-scalar  
  - **Default:** 1 (enabled) |
| Evacuate (user-defined) | Indicates if VCS initiates an automatic failover when user issues `hastop -local-evacuate`.  
  - **Type and dimension:** boolean-scalar  
  - **Default:** 1 |
### Table C-3  Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| Evacuating (system use only) | Indicates the node ID from which the service group is being evacuated.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| Failover (system use only) | Indicates service group is in the process of failing over.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: Not applicable |
| FailOverPolicy (user-defined) | Sets the policy VCS uses to determine which system a group fails over to if multiple systems exist. This attribute can take the following values:  
  Priority—The system defined as the lowest priority in the SystemList attribute is chosen.  
  Load—The system defined with the least value in the system's Load attribute is chosen.  
  RoundRobin—Systems are chosen according to how many active service groups they are hosting. The system with the least number of active service groups is chosen first.  
  ■ Type and dimension: string-scalar  
  ■ Default: Priority |
| FaultPropagation (user-defined) | Specifies if VCS should propagate the fault up to parent resources and take the entire service group offline when a resource faults.  
  The value 1 indicates that when a resource faults, VCS fails over the service group, if the group's AutoFailOver attribute is set to 1. If The value 0 indicates that when a resource faults, VCS does not take other resources offline, regardless of the value of the Critical attribute. The service group does not fail over on resource fault.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 1 |
| FromQ (system use only) | Indicates the system name from which the service group is failing over. This attribute is specified when service group failover is a direct consequence of the group event, such as a resource fault within the group or a group switch.  
  ■ Type and dimension: string-association  
  ■ Default: Not applicable |
<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| Frozen (user-defined)    | Disables all actions, including autostart, online and offline, and failover, except for monitor actions performed by agents. (This convention is observed by all agents supplied with VCS.)  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 0 (not frozen) |
| GroupOwner (user-defined) | VCS sends email notification to the person designated in this attribute when an event occurs related to the service group. VCS also logs the owner name when an event occurs.  
  Make sure to set the severity level at which you want notifications to the group owner to at least one recipient defined in the SmtpRecipients attribute of the NotifierMngr agent.  
  For example, to send notifications at the Information severity level to user groupadmin@yourcompany.com:  
  ■ Set the GroupOwner attribute to groupadmin@company.com.  
  ■ In the list of SMTP recipients in the NotifierMngr configuration, set the associated notification severity for at least one user to Information.  
    NotifierMngr notification {  
      SmtpRecipients = { "admin@company.com" = Information, "superadmin@company.com" = Error}  
      SmtpServer = "mail.company.com"  
    }  
  ■ Type and dimension: string-scalar  
  ■ Default: If GroupOwner is not specified in main.cf, the default value is “unknown”. |
| Guests (user-defined)     | List of operating system user accounts that have Guest privileges on the service group.  
  This attribute applies to clusters running in secure mode.  
  ■ Type and dimension: string-keylist  
  ■ Default: "" |
## Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntentOnline</td>
<td>Indicates whether to keep service groups online or offline. VCS sets this attribute to 1 if an attempt has been made to bring the service group online. For failover groups, VCS sets this attribute to 0 when the group is taken offline. For parallel groups, it is set to 0 for the system when the group is taken offline or when the group faults and can fail over to another system. VCS sets this attribute to 2 for failover groups if VCS attempts to autostart a service group; for example, attempting to bring a service group online on a system from AutoStartList.</td>
</tr>
<tr>
<td>LastSuccess</td>
<td>Indicates the time when service group was last brought online.</td>
</tr>
<tr>
<td>Load</td>
<td>Integer value expressing total system load this group will put on a system. For example, the administrator may assign a value of 100 to a large production SQL and 15 to a Web server.</td>
</tr>
<tr>
<td>ManageFaults</td>
<td>Specifies if VCS manages resource failures within the service group by calling the Clean function for the resources. This attribute can take the following values. NONE—VCS does not call the Clean function for any resource in the group. User intervention is required to handle resource faults. See “Controlling Clean behavior on resource faults” on page 480.</td>
</tr>
<tr>
<td>ManualOps</td>
<td>Indicates if manual operations are allowed on the service group.</td>
</tr>
</tbody>
</table>

### Table C-3  Service group attributes

<table>
<thead>
<tr>
<th><strong>Service Group Attributes</strong></th>
<th><strong>Definition</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>MigrateQ (system use only)</td>
<td>Indicates the system from which the service group is migrating. This attribute is specified when group failover is an indirect consequence (in situations such as a system shutdown or another group faults and is linked to this group).</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: string-association</td>
</tr>
<tr>
<td></td>
<td>■ Default: Not applicable</td>
</tr>
<tr>
<td>NumRetries (system use only)</td>
<td>Indicates the number of attempts made to bring a service group online. This attribute is used only if the attribute OnlineRetryLimit is set for the service group.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: Not applicable</td>
</tr>
<tr>
<td>OnlineAtUnfreeze (system use only)</td>
<td>When a node or a service group is frozen, the OnlineAtUnfreeze attribute specifies how an offline service group reacts after it or a node is unfrozen.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: Not applicable</td>
</tr>
<tr>
<td>OnlineRetryInterval (user-defined)</td>
<td>Indicates the interval, in seconds, during which a service group that has successfully restarted on the same system and faults again should be failed over, even if the attribute OnlineRetryLimit is non-zero. This prevents a group from continuously faulting and restarting on the same system.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 0</td>
</tr>
<tr>
<td>OnlineRetryLimit (user-defined)</td>
<td>If non-zero, specifies the number of times the VCS engine tries to restart a faulted service group on the same system on which the group faulted, before it gives up and tries to fail over the group to another system.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 0</td>
</tr>
<tr>
<td>OperatorGroups (user-defined)</td>
<td>List of operating system user groups that have Operator privileges on the service group. This attribute applies to clusters running in secure mode.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: string-keylist</td>
</tr>
<tr>
<td></td>
<td>■ Default: &quot;&quot;</td>
</tr>
<tr>
<td>Service Group Attributes</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------</td>
</tr>
</tbody>
</table>
| Operators (user-defined) | List of VCS users with privileges to operate the group. A Group Operator can only perform online/offline, and temporary freeze/unfreeze operations pertaining to a specific group. See “About the VCS user privilege model” on page 67.  
  ■ Type and dimension: string-keylist  
  ■ Default: "" |
| Parallel (user-defined)  | Indicates if service group is failover (0), parallel (1), or hybrid(2).  
  ■ Type and dimension: integer-scalar  
  ■ Default: 0 |
| PathCount (system use only) | Number of resources in path not yet taken offline. When this number drops to zero, the engine may take the entire service group offline if critical fault has occurred.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| PreOnline (user-defined) | Indicates that the VCS engine should not online a service group in response to a manual group online, group autostart, or group failover. The engine should instead run the PreOnline trigger. See “preonline event trigger” on page 559.  
  You can set a local (per-system) value for this attribute to control the firing of PreOnline triggers on each node in the cluster. This attribute is strictly a per system attribute, then you must set the value for each system.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 0 |
| PreOnlining (system use only) | Indicates that VCS engine invoked the preonline script; however, the script has not yet returned with group online.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
### Table C-3  Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| PreonlineTimeout (user-defined) | Defines the maximum amount of time in seconds the preonline script takes to run the command \texttt{hagrp -online -nopre} for the group. Note that HAD uses this timeout during evacuation only. For example, when a user runs the command \texttt{hastop -local -evacuate} and the Preonline trigger is invoked on the system on which the service groups are being evacuated.  
- Type and dimension: integer-scalar  
- Default: 300 |
| Prerequisites (user-defined) | An unordered set of name=value pairs denoting specific resources required by a service group. If prerequisites are not met, the group cannot go online. The format for Prerequisites is: \texttt{Prerequisites()} = \{\text{Name=value, name2=value2}\}. Names used in setting Prerequisites are arbitrary and not obtained from the system. Coordinate name=value pairs listed in Prerequisites with the same name=value pairs in Limits(). See “About system limits and service group prerequisites” on page 500.  
- Type and dimension: integer-association |
| PrintTree (user-defined) | Indicates whether or not the resource dependency tree is written to the configuration file. The value 1 indicates the tree is written.  
**Note:** For very large configurations, the time taken to print the tree and to dump the configuration is high.  
- Type and dimension: boolean-scalar  
- Default: 1 |
| Priority (user-defined) | Enables users to designate and prioritize the service group. VCS does not interpret the value; rather, this attribute enables the user to configure the priority of a service group and the sequence of actions required in response to a particular event.  
- Type and dimension: integer-scalar  
- Default: 0 |
| Probed (system use only) | Indicates whether all enabled resources in the group have been detected by their respective agents.  
- Type and dimension: boolean-scalar  
- Default: Not applicable |
<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| ProbesPending (system use only) | The number of resources that remain to be detected by the agent on each system.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable |
| Responding (system use only) | Indicates VCS engine is responding to a failover event and is in the process of bringing the service group online or failing over the node.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable |
| Restart (system use only) | For internal use only.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable |
| SourceFile (system use only) | File from which the configuration is read. Do not configure this attribute in main.cf.  
  Make sure the path exists on all nodes before running a command that configures this attribute.  
  Make sure the path exists on all nodes before configuring this attribute.  
  - Type and dimension: string-scalar  
  - Default: ./main.cf |
<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>State (system use only)</td>
<td>Group state on each system:&lt;br&gt; OFFLINE—All non-persistent resources are offline.&lt;br&gt; ONLINE—All resources whose AutoStart attribute is equal to 1 are online.&lt;br&gt; FAULTED—At least one critical resource in the group is faulted or is affected by a fault.&lt;br&gt; PARTIAL—At least one, but not all, resources with Operations=OnOff is online, and not all AutoStart resources are online.&lt;br&gt; STARTING—Group is attempting to go online.&lt;br&gt; STOPPING—Group is attempting to go offline.&lt;br&gt; A group state may be a combination of the multiple states described above. For example, OFFLINE</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar&lt;br&gt; ■ Default: Not applicable.</td>
</tr>
<tr>
<td>SystemList (user-defined)</td>
<td>List of systems on which the service group is configured to run and their priorities. Lower numbers indicate a preference for the system as a failover target.&lt;br&gt; <strong>Note:</strong> You must define this attribute prior to setting the AutoStartList attribute.&lt;br&gt; ■ Type and dimension: integer-association&lt;br&gt; ■ Default: &quot;&quot; (none)</td>
</tr>
<tr>
<td>SystemZones (user-defined)</td>
<td>Indicates the virtual sublists within the SystemList attribute that grant priority in failing over. Values are string/integer pairs. The string key is the name of a system in the SystemList attribute, and the integer is the number of the zone. Systems with the same zone number are members of the same zone. If a service group faults on one system in a zone, it is granted priority to fail over to another system within the same zone, despite the policy granted by the FailOverPolicy attribute.&lt;br&gt; ■ Type and dimension: integer-association&lt;br&gt; ■ Default: &quot;&quot; (none)</td>
</tr>
</tbody>
</table>
## VCS attributes

### Service group attributes

<table>
<thead>
<tr>
<th>Service Group Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| Tag (user-defined)       | Identifies special-purpose service groups created for specific VCS products.  
  - Type and dimension: string-scalar  
  - Default: "" |
| TargetCount (system use only) | Indicates the number of target systems on which the service group should be brought online.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable. |
| TFrozen (user-defined)   | Indicates if service groups can be brought online or taken offline on nodes in the cluster. Service groups cannot be brought online or taken offline if the value of the attribute is 1.  
  - Type and dimension: boolean-scalar  
  - Default: 0 (not frozen) |
| ToQ (system use only)    | Indicates the node name to which the service is failing over. This attribute is specified when service group failover is a direct consequence of the group event, such as a resource fault within the group or a group switch.  
  - Type and dimension: string-association  
  - Default: Not applicable |
| TriggerEvent (system use only) | For internal use only.  
  - Type and dimension: boolean-scalar  
  - Default: Not applicable |
| TriggerResFault (user-defined) | Defines whether VCS invokes the resfault trigger when a resource faults. The value 0 indicates that VCS does not invoke the trigger.  
  See “resfault event trigger” on page 562.  
  - Type and dimension: integer-scalar  
  - Default: 1 |
| TriggerResStateChange (user-defined) | Determines whether or not to invoke the resstatechange trigger if resource state changes.  
  See “resstatechange event trigger” on page 564.  
  - Type and dimension: boolean-scalar  
  - Default: 0 (disabled) |
Table C-3  Service group attributes

# System attributes

Table C-4 lists the system attributes.

Table C-4  System attributes

<table>
<thead>
<tr>
<th><strong>System Attributes</strong></th>
<th><strong>Definition</strong></th>
</tr>
</thead>
</table>
| AgentsStopped *(system use only)*             | This attribute is set to 1 on a system when all agents running on the system are stopped.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| AvailableCapacity *(system use only)*         | Indicates system's available capacity when trigger is fired. If this value is negative, the argument contains the prefix % (percentage sign); for example, %-4.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| Capacity *(user-defined)*                     | Value expressing total system load capacity. This value is relative to other systems in the cluster and does not reflect any real value associated with a particular system.  
  For example, the administrator may assign a value of 200 to a 16-processor machine and 100 to an 8-processor machine.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 100 |
| ConfigBlockCount *(system use only)*          | Number of 512-byte blocks in configuration when the system joined the cluster.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| ConfigCheckSum *(system use only)*            | Sixteen-bit checksum of configuration identifying when the system joined the cluster.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| ConfigDiskState *(system use only)*           | State of configuration on the disk when the system joined the cluster.  
  ■ Type and dimension: integer-scalar  
  ■ Default: Not applicable |
| ConfigFile *(user-defined)*                   | Directory containing the configuration files.  
  ■ Type and dimension: string-scalar  
  ■ Default: “” |
The count of outstanding CONFIG_INFO messages the local node expects from a new membership message. This attribute is non-zero for the brief period during which new membership is processed. When the value returns to 0, the state of all nodes in the cluster is determined.

- Type and dimension: integer-scalar
- Default: Not applicable

Last modification date of configuration when the system joined the cluster.

- Type and dimension: integer-scalar
- Default: Not applicable

Indicates the system’s CPU usage by CPU percentage utilization. This attribute’s value is valid if the Enabled value in the CPUUsageMonitoring attribute (below) equals 1. The value of this attribute is updated when there is a change of five percent since the last indicated value.

- Type and dimension: integer-scalar
- Default: Not applicable

Monitors the system’s CPU usage using various factors. The values for ActionTimeLimit and NotifyTimeLimit represent the time in seconds. The values for ActionThreshold and NotifyThreshold represent the threshold in terms of CPU percentage utilization.

See “Monitoring CPU usage” on page 671.

This attribute will be deprecated in a future release. VCS monitors system resources on startup.

- Type and dimension: string-association
- Default: Enabled = 0, NotifyThreshold = 0, NotifyTimeLimit = 0, ActionThreshold = 0, ActionTimeLimit = 0, Action = NONE.

System-maintained calculation of current value of Limits.

CurrentLimits = Limits - (additive value of all service group Prerequisites).

- Type and dimension: integer-association
- Default: Not applicable

### System attributes

#### LicenseType (system use only)
Indicates the license type of the base VCS key used by the system. Possible values are:
- 0—DEMO
- 1—PERMANENT
- 2—PERMANENT_NODE_LOCK
- 3—DEMO_NODE_LOCK
- 4—NFR
- 5—DEMO_EXTENSION
- 6—NFR_NODE_LOCK
- 7—DEMO_EXTENSION_NODE_LOCK

- Type and dimension: integer-scalar
- Default: Not applicable

#### Limits (user-defined)
An unordered set of name=value pairs denoting specific resources available on a system. Names are arbitrary and are set by the administrator for any value. Names are not obtained from the system.

The format for Limits is:
Limits = {Name=Value, Name2=Value2}.

- Type and dimension: integer-association
- Default: ""

#### LinkHbStatus (system use only)
Indicates status of private network links on any system.

Possible values include the following:
LinkHbStatus = { nic1 = UP, nic2 = DOWN }

Where the value UP for nic1 means there is at least one peer in the cluster that is visible on nic1.

Where the value DOWN for nic2 means no peer in the cluster is visible on nic2.

- Type and dimension: string-association
- Default: ""

#### LLTNodeId (system use only)
Displays the node ID defined in the file %VCS_HOME%\comms\llt\llttab.txt.

- Type and dimension: integer-scalar
- Default: Not applicable

## System Attributes

<table>
<thead>
<tr>
<th>System Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoadTimeCounter (system use only)</td>
<td>System-maintained internal counter of how many seconds the system load has been above LoadWarningLevel. This value resets to zero anytime system load drops below the value in LoadWarningLevel.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: Not applicable</td>
</tr>
<tr>
<td>LoadTimeThreshold (user-defined)</td>
<td>How long the system load must remain at or above LoadWarningLevel before the LoadWarning trigger is fired. If set to 0 overload calculations are disabled.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 600</td>
</tr>
<tr>
<td>LoadWarningLevel (user-defined)</td>
<td>A percentage of total capacity where load has reached a critical limit. If set to 0 overload calculations are disabled. For example, setting LoadWarningLevel = 80 sets the warning level to 80 percent. The value of this attribute can be set from 1 to 100. If set to 1, system load must equal 1 percent of system capacity to begin incrementing the LoadTimeCounter. If set to 100, system load must equal system capacity to increment the LoadTimeCounter.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 80</td>
</tr>
<tr>
<td>NoAutoDisable (system use only)</td>
<td>When set to 0, this attribute autodisables service groups when the VCS engine is taken down. Groups remain autodisabled until the engine is brought up (regular membership). This attribute's value is updated whenever a node joins (gets into RUNNING state) or leaves the cluster. This attribute cannot be set manually.</td>
</tr>

### Table C-4 System attributes

<table>
<thead>
<tr>
<th>System Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ShutdownTimeout</td>
<td>Determines whether to treat system reboot as a fault for service groups running on the system.</td>
</tr>
<tr>
<td></td>
<td>On many systems, when a reboot occurs the processes are stopped first, then the system goes down. When the VCS engine is stopped, service groups that include the failed system in their SystemList attributes are autodisabled. However, if the system goes down within the number of seconds designated in ShutdownTimeout, service groups previously online on the failed system are treated as faulted and failed over. Symantec recommends that you set this attribute depending on the average time it takes to shut down the system.</td>
</tr>
<tr>
<td></td>
<td>If you do not want to treat the system reboot as a fault, set the value for this attribute to 0.</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
### Table C-4  System attributes

<table>
<thead>
<tr>
<th>System Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SystemOwner</td>
<td>This attribute is used for VCS email notification and logging. VCS sends email notification to the person designated in this attribute when an event occurs related to the system. VCS also logs the owner name when an event occurs.</td>
</tr>
</tbody>
</table>
|                     | ■ Type and dimension: string-scalar  
|                     | ■ Default: “unknown”                                                               |
| TFrozen             | Indicates a service group that can be brought online on a node. Service group cannot be brought online if the value of this attribute is 1. |
|                     | ■ Type and dimension: boolean-scalar  
|                     | ■ Default: 0                                                                        |
| TRSE                | Indicates in seconds the time to Regular State Exit. Time is calculated as the duration between the events of VCS losing port h membership and of VCS losing port a membership of GAB. |
|                     | ■ Type and dimension: integer-scalar  
|                     | ■ Default: Not applicable                                                           |
| UpDownState         | This attribute has four values:  |
|                     | 0 (down): System is powered off, or GAB and LLT are not running on the system.  |
|                     | 1 (Up but not in cluster membership): GAB and LLT are running but the VCS engine is not.  |
|                     | 2 (up and in jeopardy): The system is up and part of cluster membership, but only one network link (LLT) remains.  |
|                     | 3 (up): The system is up and part of cluster membership, and has at least two links to the cluster. |
|                     | ■ Type and dimension: integer-scalar  
|                     | ■ Default: Not applicable                                                           |
| UserInt             | Stores integer values you want to use. VCS does not interpret the value of this attribute.                                         |
|                     | ■ Type and dimension: integer-scalar  
|                     | ■ Default: 0                                                                        |
Table C-5 lists the cluster attributes.

<table>
<thead>
<tr>
<th>Cluster Attributes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdministratorGroups (user-defined)</td>
<td>List of operating system user account groups that have administrative privileges on the cluster. This attribute applies to clusters running in secure mode.</td>
</tr>
<tr>
<td>Administrators (user-defined)</td>
<td>Contains list of users with Administrator privileges.</td>
</tr>
</tbody>
</table>
### AuthorizationControl

This attribute applies to clusters running in secure mode. It defines how VCS assigns cluster privileges to operating system (OS) users that have local or domain administrator privileges. The OS users must be defined as VCS users before modifying the attribute's default value.

The attribute can take the following values:

- **DEFAULT**: Assigns cluster administrator privileges to users with local administrator and domain administrator privileges.
- **NONE**: Does not assign cluster administrator privileges to users with local administrator and domain administrator privileges. Windows services running under local system accounts get cluster administrator privileges when they connect to VCS. You can override this setting by defining privileges for local and domain administrators in the VCS user list.
- **LOCAL**: Assigns cluster administrator privileges to local administrators, but not to domain administrators. You can override this setting by defining privileges for domain administrators in the VCS user list.
- **GLOBAL**: Assigns cluster administrator privileges to domain administrators, but not to local administrators. You can override this setting by defining privileges for local administrators in the VCS user list.

### AutoStartTimeout

If the local cluster cannot communicate with one or more remote clusters, this attribute specifies the number of seconds the VCS engine waits before initiating the AutoStart process for an AutoStart global service group.

- **Type and dimension**: integer-scalar
- **Default**: 150 seconds

### BackupInterval

Time period in minutes after which VCS backs up the configuration files if the configuration is in read-write mode.

The value 0 indicates VCS does not back up configuration files. Set this attribute to at least 3.

See “Scheduling automatic backups for VCS configuration files” on page 269.

- **Type and dimension**: integer-scalar
- **Default**: 0

### Table C-5  Cluster attributes

<table>
<thead>
<tr>
<th>Cluster Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| ClusState          | Indicates the current state of the cluster.  
| (system use only)  |  
|                    | ■ Type and dimension: integer-scalar  
|                    | ■ Default: Not applicable.  |
| ClusterAddress     | Specifies the cluster’s virtual IP address (used by a remote cluster when connecting to the local cluster).  
| (user-defined)     |  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: ""  |
| ClusterLocation    | Specifies the location of the cluster.  
| (user-defined)     |  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: ""  |
| ClusterName        | The name of cluster.  
| (user-defined)     |  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: ""  |
| ClusterOwner       | This attribute is used for VCS notification; specifically, VCS sends notifications to persons designated in this attribute when an event occurs related to the cluster.  
| (user-defined)     |  
|                    | See “About VCS event notification” on page 536.  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: “unknown”  |
| ClusterTime        | The number of seconds since January 1, 1970. This is defined by the lowest node in running state.  
| (system use only)  |  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: Not applicable  |
| ClusterUUID        | Unique ID assigned to the cluster by Availability Manager.  
| (system use only)  |  
|                    | ■ Type and dimension: string-scalar  
|                    | ■ Default: Not applicable  |
| CompareRSM         | Indicates if VCS engine is to verify that replicated state machine is consistent. This can be set by running the hadebug command.  
| (system use only)  |  
|                    | ■ Type and dimension: integer-scalar  
|                    | ■ Default: 0  |
| ConnectorState     | Indicates the state of the wide-area connector (wac). If 0, wac is not running. If 1, wac is running and communicating with the VCS engine.  
| (system use only)  |  
|                    | ■ Type and dimension: integer-scalar  
|                    | ■ Default: Not applicable.  |
### Table C-5  Cluster attributes

<table>
<thead>
<tr>
<th>Cluster Attributes</th>
<th>Definition</th>

<tbody>
<tr>
<td>CounterInterval</td>
<td>Intervals counted by the attribute GlobalCounter indicating approximately how often a broadcast occurs that will cause the GlobalCounter attribute to increase.</td>
</tr>
<tr>
<td></td>
<td>The default value of the GlobalCounter increment can be modified by changing CounterInterval. If you increase this attribute to exceed five seconds, consider increasing the default value of the ShutdownTimeout attribute.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: 5</td>
</tr>
<tr>
<td>CredRenewFrequency</td>
<td>The number of days after which the VCS engine renews its credentials with the authentication broker. For example, the value 5 indicates that credentials are renewed every 5 days; the value 0 indicates that credentials are not renewed.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default = 0</td>
</tr>
<tr>
<td>DumpingMembership</td>
<td>Indicates that the engine is writing to disk.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: integer-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: Not applicable.</td>
</tr>
<tr>
<td>EnginePriority</td>
<td>The priority in which HAD runs.</td>
</tr>
<tr>
<td></td>
<td>■ Type and dimension: string-scalar</td>
</tr>
<tr>
<td></td>
<td>■ Default: &quot;&quot;</td>
</tr>
<tr>
<td>EngineShutdown</td>
<td>Defines the options for the hastop command. The attribute can assume the following values:</td>
</tr>
<tr>
<td></td>
<td>Enable—Process all hastop commands. This is the default behavior.</td>
</tr>
<tr>
<td></td>
<td>Disable—Reject all hastop commands.</td>
</tr>
<tr>
<td></td>
<td>DisableClusStop—Do not process the hastop -all command; process all other hastop commands.</td>
</tr>
<tr>
<td></td>
<td>PromptClusStop—Prompt for user confirmation before running the hastop -all command; process all other hastop commands.</td>
</tr>
<tr>
<td></td>
<td>PromptLocal—Prompt for user confirmation before running the hastop -local command; reject all other hastop commands.</td>
</tr>
<tr>
<td></td>
<td>PromptAlways—Prompt for user confirmation before running any hastop command.</td>
</tr>
<tr>

</tbody>
</table>
### Cluster attributes

<table>
<thead>
<tr>
<th>Cluster Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| **GlobalCounter**        | This counter increases incrementally by one for each counter interval. It increases when the broadcast is received. VCS uses the GlobalCounter attribute to measure the time it takes to shut down a system. By default, the GlobalCounter attribute is updated every five seconds. This default value, combined with the 600-second default value of the ShutdownTimeout attribute, means if system goes down within 120 increments of GlobalCounter, it is treated as a fault. Change the value of the CounterInterval attribute to modify the default value of GlobalCounter increment.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable. |
| **Guests**               | List of operating system user accounts that have Guest privileges on the cluster. This attribute is valid clusters running in secure mode.  
  - Type and dimension: string-keylist  
  - Default: "" |
| **GroupLimit**           | Maximum number of service groups.  
  - Type and dimension: integer-scalar  
  - Default: 200 |
| **HacliUserLevel**       | This attribute has two, case-sensitive values:  
  - NONE–hacli is disabled for all users regardless of role.  
  - COMMANDROOT–hacli is enabled for root only.  
  **Note:** The command haclus -modify HacliUserLevel can be executed by root only.  
  - Type and dimension: string-scalar  
  - Default: NONE |
| **LockMemory**           | Controls the locking of VCS engine pages in memory. This attribute has the following values. Values are case-sensitive:  
  - ALL: Locks all current and future pages.  
  - CURRENT: Locks current pages.  
  - NONE: Does not lock any pages.  
  - Type and dimension: string-scalar  
  - Default: ALL |
### Cluster Attributes

<table>
<thead>
<tr>
<th>Cluster Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| **LogSize**<br>(user-defined) | Indicates the size of engine log file in bytes.  
Minimum value is 65536 (equal to 64KB)  
Maximum value = 134217728 (equal to 128MB)  
Default value = 33554432 (equal to 32MB)  
  ■ Type and dimensions: integer - scalar  
  ■ Default value = 33554432 |
| **Notifier**<br>(system use only) | Indicates the status of the notifier in the cluster; specifically:  
State—Current state of notifier, such as whether or not it is connected to VCS.  
Host—The host on which notifier is currently running or was last running. Default = None  
Severity—The severity level of messages queued by VCS for notifier. Values include Information, Warning, Error, and SevereError. Default = Warning  
Queue—The size of queue for messages queued by VCS for notifier.  
  ■ Type and dimension: string-association  
  ■ Default: Different values for each parameter. |
| **OperatorGroups**<br>(user-defined) | List of operating system user groups that have Operator privileges on the cluster.  
This attribute is valid clusters running in secure mode.  
  ■ Type and dimension: string-keylist  
  ■ Default: "" |
| **Operators**<br>(user-defined) | List of users with Cluster Operator privileges.  
  ■ Type and dimension: string-keylist  
  ■ Default: "" |
| **PanicOnNoMem**<br>(user-defined) | Indicate the action that you want VCS engine (HAD) to take if it cannot receive messages from GAB due to low-memory.  
  ■ If the value is 0, VCS exits with warnings. If the value is 1, VCS calls the GAB library routine to panic the system.  
  ■ Default: 0 |
| **PrintMsg**<br>(user-defined) | Enables logging TagM messages in engine log if set to 1.  
  ■ Type and dimension: boolean-scalar  
  ■ Default: 0 |
<table>

Heartbeat attributes (for global clusters)

Table C-6 lists the heartbeat attributes. These attributes apply to global clusters.

<table>
<thead>
<tr>
<th>Heartbeat Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| AgentState (system use only) | The state of the heartbeat agent.  
  ■ Type and dimension: integer-scalar  
  ■ Default: INIT |
| Arguments (user-defined) | List of arguments to be passed to the agent functions. For the icmp agent, this attribute can be the IP address of the remote cluster.  
  ■ Type and dimension: string-vector  
  ■ Default: "" |
| AYAInterval (user-defined) | The interval in seconds between two heartbeats.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 60 seconds |
| AYARetryLimit (user-defined) | The maximum number of lost heartbeats before the agent reports that heartbeat to the cluster is down.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 3 |
| AYATimeout (user-defined) | The maximum time (in seconds) that the agent will wait for a heartbeat AYA function to return ALIVE or DOWN before being canceled.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 30 |
| CleanTimeOut (user-defined) | Number of seconds within which the Clean function must complete or be canceled.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 300 seconds |
| ClusterList (user-defined) | List of remote clusters.  
  ■ Type and dimension: string-keylist  
  ■ Default: "" |
| InitTimeout (user-defined) | Number of seconds within which the Initialize function must complete or be canceled.  
  ■ Type and dimension: integer-scalar  
  ■ Default: 300 seconds |
<table>
<thead>
<tr>
<th>Heartbeat Attributes</th>
<th>Definition</th>
</tr>
</thead>
</table>
| LogDbg (user-defined) | The log level for the heartbeat.  
  - Type and dimension: string-keylist  
  - Default: "" |
| State                | The state of the heartbeat.  
  - Type and dimension: integer-scalar  
  - Default: Not applicable |
| StartTimeout (user-defined) | Number of seconds within which the Start function must complete or be canceled.  
  - Type and dimension: integer-scalar  
  - Default: 300 seconds |
| StopTimeout (user-defined) | Number of seconds within which the Stop function must complete or be canceled without stopping the heartbeat.  
  - Type and dimension: integer-scalar  
  - Default: 300 seconds |
VCS attributes

Heartbeat attributes (for global clusters)
Administering Symantec Web Server

- About Symantec Web Server
- Getting Started
- Configuring ports for VRTSweb
- Managing VRTSweb SSL certificates
- Configuring SMTP notification for VRTSweb
- Configuring logging for VRTSweb
- Modifying the maximum heap size for VRTSweb
About Symantec Web Server

Symantec Web Server (VRTSweb) is a Web Server component shared by various Symantec Web consoles, including Veritas Cluster Server and Veritas Volume Replicator.

This document describes how to administer VRTSweb and provides instructions for common configuration tasks. Note that changes to the VRTSweb configuration apply to all Web consoles sharing the Web server.

The Web server is installed at the following path:
Windows: C:\Program Files\Veritas\VRTSweb.

To administer the VRTSweb from the command line, you must run commands from the following paths:
Windows: C:\Program Files\Veritas\VRTSweb\bin\

Getting Started

Connect to the Web server to start administering it.

To connect to Symantec Web Server

1. Access the Web server using the configured port number, for example, http:/ /hostname:8181/.

2. Accept the certificate by Symantec.

- To view and select the available Web consoles, click the Home.
- To view and configure ports, SMTP recipients, SMTP servers, and logging, click Configuration.
3. Review the information in the **Configuration** tab:

- **Configured Ports**—Lists information about the configured ports.
- **SMTP Recipients**—Displays information about configured SMTP recipients and the SMTP server.
- **Logging**—Lists the log levels for various Web server components.
Configuring ports for VRTSweb

You can view, add, edit, or remove ports for VRTSweb.

About VRTSweb ports

By default, VRTSweb serves HTML content on the following ports:

- 8181 (HTTP)—Non-secure port, used for backward compatibility. VRTSweb redirects users to the secure port.
- 8443 (HTTPS)—Secure SSL port. VRTSweb presents a self-signed SSL certificate (issued by Symantec) to the browser. You must accept the certificate before accessing the secure Web consoles. The SSL protocol prevents malicious users from sniffing Web console data from the network.
- 14300—Administrative port.

If you use these ports for another application on the system, configure VRTSweb to use different ports.

Retrieving the list of VRTSweb ports

Retrieve the list of ports that are configured for VRTSweb.

To retrieve the list of ports from the command line

On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

```
webgui listports
```

The output displays the list of configured ports and their protocols.

To retrieve the list of ports from the Web Console

1. Access the Web server using the configured port number, for example, http:/hostname:8181/.
2. Click the Configuration tab.

The Configured Ports table on the right side of the Configuration page lists the ports.
Adding ports for VRTSweb

Add ports for use by VRTSweb.

To add a port from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

  ```
  webgui addport portno protocol bind_ip_address
  ```

  - `portno`—The port number to be added.
  - `protocol`—The protocol for the port. HTTP specifies a normal HTTP port, HTTPS specifies a secure SSL port.
  - Web servers using the HTTP port can be accessed at `http://hostname:portno/`.
  - Web servers using the HTTPS port can be accessed at `https://hostname:portno/`.
  - `bind_ip_address`—Optional variable. Specifies that the new port be bound to a particular IP address instead of each IP address on the system. Use this option to restrict Web server access to specific administrative subnets. The IP address must be available on the system before the Web server starts.

  For example:

  ```
  addport 443 HTTPS 1.1.2
  ```

To add a port from the Web console

1. Access the Web server using the configured port number, for example, `http://hostname:8181/`.
2. Click the **Configuration** tab.
3. Click **Add Port** on the left side of the Configuration page.
4 In the Add Port pane:

```
<table>
<thead>
<tr>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Port</td>
</tr>
<tr>
<td>This page lets you add a new port to the web server. To add a secure port, select the https protocol. IP address is optional. If not specified, the specified port will be bound to all IP addresses on the machine.</td>
</tr>
</tbody>
</table>

- Port Number: [text field]
- Protocol: [radio buttons] http, https
- IP Address (optional): [text field]
- Username*: [text field]
- Password: [text field]
* Should belong to the group "root" on vsftpd

- Enter the port number to be added.
- Choose the HTTP option to add a normal port; choose the HTTPS option to add a secure SSL port.
  - Web servers using the HTTP port can be accessed at http://hostname:portno/.
  - Web servers using the HTTPS port can be accessed at https://hostname:portno/.
- Enter an IP address to bind the new port to a specific IP address instead of each IP address on the system. The IP address available on the system before starting the Web server. Use this attribute to restrict Web server access to specific administrative subnets.
- Enter the name and password for a user having superuser (administrative) privileges on the Web server system.

5 Click **OK**.
Deleting ports

Delete unused ports from VRTSweb.

To delete a port from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
  ```bash
  webgui delport <portno> [bind_ip_address]
  ```
  The variable `portno` represents the port number to be deleted. If the port was bound to a particular IP address, use the `bind_ip_address` option.
  You must ensure that at least one port remains configured for the Web server.
  For example:
  ```bash
  webgui delport 443 101.1.1.2
  webgui delport 80
  ```

To delete a port from the Web console

1. Access the Web server on a configured port. For example, `http://hostname:8181/`
2. Click the Configuration tab.
3. Click Delete Port on the left side of the Configuration page.
4. In the Delete Port pane:
   - Enter the port number to be deleted. You cannot delete the port being used to access the Web page.
   - If the port was bound to a particular IP address, enter the IP address.
   - Enter the name and password for a user having superuser (administrative) privileges on Web server system.
5. Click OK.

Changing the administrative port

You can change the administrative port for VRTSweb only from the command line.

To change the administrative port

1. Stop the Web server:
   ```bash
   webgui stop force
   ```
2. Set the administrative port to a new value:
   ```bash
   webgui adminport new_port_no
   ```
3. Restart the Web server:
   ```bash
   webgui restart
   ```
Managing VRTSweb SSL certificates

VRTSweb presents a self-signed SSL certificate (issued by Symantec) when VRTSweb serves content over the secure port.

**Note:** Certificate management commands are available only by the command line interface. Commands that modify the certificate require a server restart.

Viewing SSL certificate information

Display information about the configured SSL certificate.

**To view information about the SSL certificate**

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
  ```
  webgui cert display
  ```

Creating a self-signed SSL certificate

Create a customized self-signed SSL certificate for VRTSweb.

**To create a self-signed SSL certificate**

1. Run the following interactive command on the system where VRTSweb is installed:
   ```
   webgui cert create
   ```
2. Follow the prompts to create a new certificate.
3. Restart the server for the new certificate to take effect.
   ```
   webgui restart
   ```
Exporting the SSL certificate to a file

You can export the public key that is associated with an SSL certificate to a file. You can then import the key to other applications to establish trust with the VRTSweb instance.

To export the SSL certificate to a file

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
  ```
  webgui cert export cert_file [rfc]
  ```
  If the VRTSweb SSL certificate does not exist, the command prompts you to create one. If you specify the RFC option, the key output is encoded in a printable format, which is defined by the Internet RFC 1421 standard.

Example (Windows):
```
%VRTSWEB_HOME%\bin> webgui cert export C:\myapp\vrtsweb.cer rfc
```

Configuring a CA-signed SSL certificate

By default, VRTSweb presents a self-signed SSL certificate every time you access VRTSweb over the SSL port. You can install a certificate signed by a Certificate Authority (CA) like Verisign.com or Thawte.com.

To configure a CA-signed SSL certificate

1. If you do not have a self-signed certificate with information that the CA can verify, create a certificate.
   ```
   webgui cert create
   ```
   See “Creating a self-signed SSL certificate” on page 804.

2. Generate a Certificate Signing Request (CSR) for the certificate. On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
   ```
   webgui cert certreq certreq_file
   ```
   The variable `certreq_file` specifies the file to which the CSR is written. The file is written using the Public-Key Cryptography Standard PKCS#10.

Example (Windows):
```
%VRTSWEB_HOME%\bin> webgui cert certreq /c:\myapp\vrtsweb.cs
```

3. Submit the CSR to a certification authority, who issues a CA-signed certificate.

4. Import the CA-issued certificate to VRTSweb. On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
   ```
   webgui import ca_cert_file
   ```
The variable `cert_file` represents the certificate that is issued by the certification authority.

Example (Windows):

```
%VRTSWEB_HOME%\bin> webgui cert import c:\myapp\vrtsweb.cer
```

Note that the import command fails if the CA root certificate is not a part of the trust store that is associated with VRTSweb. If the command fails, add the CA root certificate to the VRTSweb trust store:

```
webgui cert trust ca_root_cert_file
```

Example (Windows):

```
%VRTSWEB_HOME%\bin> webgui cert trust c:\myapp\caroot.cer
```

Once the certificate used to sign the CSR is added to VRTSweb trust store, you can import the CA-assigned certificate into VRTSweb.

5 Restart VRTSweb:

```
webgui restart
```

Cloning the VRTSweb SSL certificate

You can clone the VRTSweb SSL keypair into a keystore and use the cloned VRTSweb certificate for another application or Web server. Visit http://java.sun.com for more information about keystores.

To clone the VRTSweb SSL certificate

◆ Run the following command:

```
webgui cert clone keystore storepass alias keypass
```

If a clone keystore exists, the command renames it to keystore.old. If the VRTSweb SSL certificate does not exist, the command prompts you to create one.

Example (Windows):

```
%VRTSWEB_HOME%\bin> webgui cert clone c:\myapp\myserv.keystore

mystorepass myalias mykeypass
```
Configuring SMTP notification for VRTSweb

You can configure VRTSweb to send out email notifications about events that are associated with the Web server. For example:

- The Web server is starting/stopping [severity: INFORMATION]
- The Web console is starting/stopping [severity: INFORMATION]
- The Web server's allocated heap size very close to the maximum allowed [severity: SEVERE]

To send an email notification, VRTSweb needs to know the IP address or hostname of a configured SMTP server. The SMTP server address applies to all Web consoles running on the Web server. So you do not need to configure the SMTP server at multiple places.

Retrieving the name of the configured SMTP server

Retrieve the name of the SMTP server configured for VRTSweb.

To retrieve the name of the SMTP server from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
  
  ```
  webgui smtp getserver
  ```

  The command displays the SMTP server address or hostname, if it is configured.

To retrieve the name of the SMTP server from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/
2. Click the Configuration tab.
3. The SMTP Recipients table on the right side of the page displays the configured SMTP server.
Setting the SMTP server

Configure an SMTP server for VRTSweb.

To set the SMTP server from the command line
◆ Run any of the following commands on the system where VRTSweb is installed:
  
  ```
  webgui smtp setserver server_ip/hostname
  webgui smtp delserver
  ```

  The setserver command sets the SMTP server to the specified hostname/IP address. The delserver command deletes the SMTP server setting and disables SMTP notification.

  Example (Windows):
  ```
  %VRTSWEB_HOME%\bin> webgui smtp setserver smtphost.company.com
  %VRTSWEB_HOME%\bin> webgui smtp setserver 101.1.2.3
  %VRTSWEB_HOME%\bin> webgui smtp delserver
  ```

To set the SMTP server from the Web Console

1. Access the Web server on a configured port. For example, http://hostname:8181/
2. Click the **Configuration** tab.
3. Click **Configure SMTP Server** on the left side of the Configuration page.
4. In the Configure SMTP Server dialog box:
   ■ Enter the IP address or hostname of the SMTP server to be used for notification. An empty string disables notification.
   ■ Enter the name and password for a user having superuser (administrative) privileges on the Web server system.
   ■ Click **OK**.

Retrieving SMTP settings

Retrieve configuration information for VRTSweb SMTP notification.

To retrieve SMTP recipients from the command line
◆ On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

  ```
  webgui smtp listrcpt
  ```

  This command retrieves the email addresses of the configured recipients, the notification severity level, and the notification locale.
To retrieve SMTP recipients from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/

2. Click the Configuration tab.

3. The SMTP Recipients table on the right side of the Configuration page lists the configured SMTP recipients.

To retrieve the list of installed locales

◆ Run the following command:

    webgui smtp listlocales
Adding an SMTP recipient

Add a user to receive SMTP notifications from VRTSweb.

To add an SMTP recipient from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:
  ```bash
  webgui smtp addrcpt email
  [severity=<INFO|WARN|ERROR|SEVERE>]
  [locale=<en|any_other_installed_locale>]
  ```
  - The variable `email` represents the email address of the new recipient.
  - The optional attribute `severity` represents the threshold for receiving Web server events. It can assume one of the following values: INFO|WARN|ERROR|SEVERE. If no value is specified for this attribute, it takes the default ERROR level.
  - The optional attribute `locale` specifies the locale in which the notification is to be sent. If no value is specified for this attribute, it takes the default locale of the system.

Example (Windows):

```bash
%VRTSWEB_HOME%/bin> webgui smtp addrcpt admin@company.com
severity=INFO locale=ja_JP
%VRTSWEB_HOME%/bin> webgui smtp addrcpt admin@company.com
severity=ERROR
%VRTSWEB_HOME%/bin> webgui smtp addrcpt admin@company.com
```

To add an SMTP recipient from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/
2. Click the Configuration tab.
3. Click Add SMTP Recipient on the left side of the Configuration page.
4 In the Add SMTP Recipient dialog box:

- **Email**—Email address of the new recipient.
- **Severity**—Threshold for receiving Web server events. Select one of the following values: INFO|WARN|ERROR|SEVERE.
- **Locale**—The locale in which notification is to be sent.
- **Username**—User having superuser (administrative) privileges on the Web server system.
- **Password**—Password for the superuser.

5 Click **OK**.
Deleting an SMTP recipient

Delete an SMTP recipient to prevent VRTSweb from sending notifications to the recipient.

To delete an SMTP recipient from the command line

◆ On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

```
webgui smtp delrcpt email
```

The variable `email` represents the email address of the recipient to be deleted.

For example:

```
webgui smtp delrcpt admin@company.com
```

To delete an SMTP recipient from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/
2. Click the Configuration tab.
3. Click Delete SMTP Recipient on the left side of the Configuration page.
4. In the Delete SMTP Recipient dialog box:
   a. Enter the email address of the recipient to be deleted.
   b. Enter the name and password for a user having superuser (administrative) privileges on the Web server system.
5. Click OK.
Configuring logging for VRTSweb

You can configure the amount of logs that individual VRTSWeb components generate. VRTSweb comprises the following components:

- Web server
- Web applications
- Other components

You can set the logging threshold for each component separately. The lower the threshold, the more are the logs generated. Symantec recommends setting log levels to lower values only for debugging.

Most of the logs are located at:

%VRTSWEB_HOME%\log (for Windows),

Individual Symantec Web consoles choose their own locations for their logs. See the documentation for the specific Web console for more information.

Retrieving log levels

Display the current settings for VRTSweb logging.

To retrieve log levels from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

  \webgui\log

  This returns the logging thresholds for various components and the limit and rollover count of various log files for VRTSweb.

To retrieve log levels from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/
2. Click the Configuration tab.
3. The Logging table on the right side of the Configuration page lists the log levels for various components of the Web server. The table does not display the limit and rollover count of various log files; you must use the command line to retrieve this information.
Modifying log levels for VRTSweb

Customize the log levels for VRTSweb.

To modify log levels from the command line

- On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

  `webgui log [server=level] [webapps=level] [other=level]`

  You can specify any of the following values for the variable `level` for each Web server component:
  FINE|FINER|FINEST|CONFIG|INFO|WARNING|SEVERE.

  Set the level to a lower value to generate more logs. FINEST is the lowest level while SEVERE is the highest level.

  For example:

  `webgui log server=FINEST webapps=INFO Other=ERROR`

  `webgui log server=INFO`
To modify log levels from the Web console

1. Access the Web server on a configured port. For example, http://hostname:8181/

2. Click the **Configuration** tab.

3. Click **Configure Logging** on the left side of the Configuration page.

4. In the Configure Logging dialog box:

   - Select the logging levels for the Web server, Web applications, and for other components.
   - Enter the name and password for a user having superuser privileges on the Web server system.

5. Click **OK**.
Modifying size limit and rollover count for VRTSweb logs

You can modify the maximum size limit and rollover count for logs maintained by VRTSweb only from the command line.

To modify the size limit and rollover count for logs

On the system where VRTSweb is installed, run the following command from the VRTSweb install directory:

```bash
webgui log [vrtsweb_size=size] [vrtsweb_count=count]
[command_size=size] [command_count=count]
[binary_size=size] [binary_count=count]
[jvm_size=size] [jvm_count=count]
[protocol_client_size=size] [protocol_client_count=count]
[protocol_server_size=size] [protocol_server_count=count]
[command_size=size] [command_count=count]
[out_size=size] [out_count=count]
[err_size=size] [err_count=count]
[webapps_size=size] [webapps_count=count]
```

For example:

```bash
webgui log vrtsweb_size=100000 vrtsweb_count=4
webgui log err_size=200000
webgui log webapps_count=4
```

The following table describes the command parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vrtsweb_size</td>
<td>The size of the file _vtsweb.log, which contains the Web server logs and the tomcat container related logs.</td>
</tr>
<tr>
<td>vrtsweb_count</td>
<td>The count for the file _vtsweb.log.</td>
</tr>
<tr>
<td>command_size</td>
<td>The size of the file _command.log, which contains the logs related to administrative commands.</td>
</tr>
<tr>
<td>command_count</td>
<td>The count for the file _command.log.</td>
</tr>
<tr>
<td>binary_size</td>
<td>The size of the file _binary.log, which contains the binary representation of other log files.</td>
</tr>
<tr>
<td>binary_count</td>
<td>The count for the file _binary.log.</td>
</tr>
<tr>
<td>jvm_size</td>
<td>The size of the file _jvm.log, which contains JVM-related measurements. The file records the memory that is consumed by the JVM at various times.</td>
</tr>
<tr>
<td>jvm_count</td>
<td>The count for the file _jvm.log.</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>protocol_client_size</td>
<td>The size of the file _protocol_client.log, which contains the communication sent (and received) between various utilities and the server.</td>
</tr>
<tr>
<td>protocol_client_count</td>
<td>The count for the file _protocol_client.log.</td>
</tr>
<tr>
<td>protocol_server_size</td>
<td>The size of the file _protocol_server.log, which contains the communication sent (and received) by the server to various utilities.</td>
</tr>
<tr>
<td>protocol_server_count</td>
<td>The count for the file _protocol_server.log.</td>
</tr>
<tr>
<td>out_size</td>
<td>The size of the file _out.log, which contains messages that are logged to the standard output stream of the JVM.</td>
</tr>
<tr>
<td>out_count</td>
<td>The count for the file _out.log.</td>
</tr>
<tr>
<td>err_size</td>
<td>The size of the file _err.log, which contains messages that are logged to the standard error stream of the JVM, including any stack traces.</td>
</tr>
<tr>
<td>err_count</td>
<td>The count for the file _err.log.</td>
</tr>
<tr>
<td>webapps_size</td>
<td>The default size for log files of all Web applications running VRTSweb. Individual Web applications can override this default value.</td>
</tr>
<tr>
<td>webapps_count</td>
<td>The count for log files of all Web applications running VRTSweb. Individual Web applications can override this default value.</td>
</tr>
</tbody>
</table>
Modifying the maximum heap size for VRTSweb

The default maximum allowed heap size for the VRTSWeb Java Virtual Machine (JVM) is 256MB. You may need to modify this limit for large configurations or for when a large number of consoles share the same VRTSweb instance.

You can modify the maximum heap size only from the command line.

To modify the maximum heap size

1. Type the following command:
   webgui maxheap new_size_in_MB
   For example:
   webgui maxheap 512

2. Restart the Web server after specifying a new limit.
   webgui restart

3. View the current limit.
   webgui maxheap
Accessibility and VCS

- About accessibility in VCS
- Navigation and keyboard shortcuts
- Support for accessibility settings
- Support for assistive technologies
About accessibility in VCS

Veritas Cluster Server provides shortcuts for major graphical user interface (GUI) operations and menu items. Veritas Cluster Server is compatible with operating system accessibility settings as well as a variety of assistive technologies. All manuals also are provided as accessible PDF files, and the online help is provided as HTML displayed in a compliant viewer.

Navigation and keyboard shortcuts

VCS uses standard operating system navigation keys and keyboard shortcuts. For its unique functions, VCS uses its own navigation keys and keyboard shortcuts which are documented below.

Navigation in the Java Console

The following table lists keyboard navigation rules and shortcuts used in Cluster Manager (Java Console), in addition to those provided by the operating system:

<table>
<thead>
<tr>
<th>VCS Keyboard Input</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Shift F10]</td>
<td>Opens a context-sensitive pop-up menu</td>
</tr>
<tr>
<td>[Spacebar]</td>
<td>Selects an item</td>
</tr>
<tr>
<td>[Ctrl Tab]</td>
<td>Navigates outside a table</td>
</tr>
<tr>
<td>[F2]</td>
<td>Enables editing a cell</td>
</tr>
</tbody>
</table>

Navigation in the Web Console

Cluster Management Console supports standard browser-based navigation and shortcut keys for supported browsers.

All Symantec GUIs use the following keyboard navigation standards:

- Tab moves the focus to the next active area, field, or control, following a preset sequence. Shift+Tab moves the focus in the reverse direction through the sequence.
- Ctrl+Tab exits any Console area that you internally navigate with Tab.
- Up and Down arrow keys move focus up and down the items of a list.
- Alt in combination with the underlined mnemonic letter for a field or command button shifts the focus to that field or button.
Either Enter or the Spacebar activates your selection. For example, after pressing Tab to select Next in a wizard panel, press the Spacebar to display the next screen.

Support for accessibility settings

Symantec software responds to operating system accessibility settings. Symantec products are compatible with accessibility utilities provided by operating systems.

On UNIX systems, you can change the accessibility settings using desktop preferences or desktop controls. On Windows systems, you can set accessibility options involving keyboard responsiveness, display contrast, alert sounds, and mouse operation through the Control Panel (Start > Settings > Control Panel > Accessibility Options) and through the Accessibility Wizard (Start > Programs > Accessories > Accessibility > Accessibility Wizard).

Support for assistive technologies

- Cluster Manager (Java Console) is compatible with JAWS 4.5.
- Though graphics in the documentation can be read by screen readers, setting your screen reader to ignore graphics may improve performance.
- Symantec has not tested screen readers for languages other than English.

Configuring LLT over UDP

- About configuring LLT over UDP
- When to use LLT over UDP
- LLT over UDP configuration
- Sample configuration: Direct-attached links
- Sample configuration: Links crossing IP routers
- Issues and Limitations
About configuring LLT over UDP

VCS provides the option of using LLT over the UDP (User Datagram Protocol) layer for clusters using wide-area networks and routers. UDP makes LLT packets routable and thus able to span longer distances more economically.

The VCS Cluster Configuration Wizard (VCW) provides the necessary configuration options for using LLT over the UDP. You can configure LLT over UDP while configuring the cluster using VCW.

You can also manually configure LLT over UDP using the instructions described in this appendix.

Note: LLT over UDP is not supported on IPV6.

When to use LLT over UDP

Use LLT over UDP when:

■ LLT must be used over WANs

■ When hardware, such as blade servers, do not support LLT over Ethernet

Because LLT over UDP is slower than LLT over Ethernet, LLT over UDP should only be used when the hardware configuration makes it necessary.

LLT over UDP configuration

The following is a checklist for configuring LLT over UDP. Examples are provided in the sections that follow.

■ Make sure that each NIC has an IP address configured before configuring LLT. Each link must be in a different subnet. See the examples in the following sections.

■ Make sure that each link has a unique UDP port; do not assign well-known ports.

See “Selecting UDP ports” on page 827.

■ Set the broadcast address correctly for direct-attached (non-routed) links.

■ For links that cross an IP router, disable broadcast features and specify the IP address of each link manually in the llttab file. The default path for the file is $VCS_ROOT%\comms\llt\llttab.txt

See “Sample configuration: Links crossing IP routers” on page 829.
The link command in the llttab file

The following table describes the fields of the `link` command shown in the `llttab` file examples that follow.

See “Sample configuration: Direct-attached links” on page 828.
See “Sample configuration: Links crossing IP routers” on page 829.
Note that some of these fields differ from the command for standard LLT links.

- `<tag-name>` A unique string that is used as a tag by LLT; for example `link1`, `link2`,
- `<device>` The device path of the UDP protocol; for example `udp`
- `<node-range>` Nodes using the link. “-” indicates all cluster nodes are to be configured for this link.
- `<link-type>` Type of link; must be “udp” for LLT over UDP
- `<udp-port>` Unique UDP port in range of 49152-65535 for the link.
  See “Selecting UDP ports” on page 827.
- `<MTU>` “-” is the default, which has a value of 8192. The value may be increased or decreased depending on the configuration. The `lltstat -l` command can display the current value.
- `<IP address>` IP address of the link on the local node.
- `<bcast-address>` ■ for clusters having broadcasts enabled, specify the value of the subnet broadcast address
  ■ “-” is the default for clusters spanning routers
The set-addr command in the llttab file

The `set-addr` command in the `llttab` file is required when the broadcast feature of LLT is disabled, such as when LLT must cross IP routers. The following table describes the fields of the `set-addr` command.

See “Sample configuration: Links crossing IP routers” on page 829.

- `<node-id>` The ID of the cluster node; for example, 0.
- `<link tag-name>` The string used by LLT to identify the link; for example `link1`, `link2`,...
- `<address>` IP address assigned to the link on the peer node.
Selecting UDP ports

When selecting a UDP port, select an available 16-bit integer from the range described below.

- Use available ports (that is, ports that are not in use) in the private range 49152 to 65535.
- Do not use:
  - Ports from the range of well-known ports, 0 to 1023.
  - Ports from the range of registered ports, 1024 to 49151.

To check which ports are defined as defaults for a node, examine the file C:\WINDOWS\system32\drivers\etc\services. You should also use the `netstat` command to list the ports currently in use. For example:

```
# netstat -a -p UDP
```

<table>

</tr>
</tbody>
</table>

Look in the UDP section of the output; UDP ports listed under Local Address are already in use. If a port is listed in the services file, its associated name is displayed rather than the port number in the output of the netstat command.
Sample configuration: Direct-attached links

The following illustration depicts a typical configuration of direct-attached links employing LLT over UDP.

Figure F-1 Direct-attached links employing LLT over UDP

The configuration represented by the following `llttab` file for Node 0 has directly attached crossover links or links connected through a hub or switch. These links do not cross routers.

Because LLT broadcasts requests to peer nodes to discover their addresses, the addresses of peer nodes do not need to be specified in the `llttab` file using the `set-addr` command. For direct attached links, you need to set the broadcast address of the links in the `llttab` file. Verify that the IP addresses and broadcast addresses are set correctly.

```
set-node Node0
set-cluster 1
#configure Links
#link <tag-name> <device> <node-range> <link-type> <udp port> <MTU> <IP-address> <bcast-address>
link link1 udp - udp 50000 - 192.1.2.1 192.1.2.255
link link2 udp - udp 50001 - 192.1.3.1 192.1.3.255
```

The file for Node 1 would resemble:

```
set-node Node1
set-cluster 1
#configure Links
#link <tag-name> <device> <node-range> <link-type> <udp port> <MTU> <IP-address> <bcast-address>
link link1 udp - udp 50000 - 192.1.2.2 192.1.2.255
link link2 udp - udp 50001 - 192.1.3.2 192.1.3.255
```
Sample configuration: Links crossing IP routers

The following illustration depicts a typical configuration of links crossing an IP router employing LLT over UDP. The illustration shows just two nodes of a four-node cluster.

Figure F-2   Links crossing an IP router employing LLT over UDP

The configuration represented by the following llttab file for Node 1 has links crossing IP routers. Notice that IP addresses are shown for each link on each peer node. The broadcast features are disabled because LLT is unable to broadcast requests for addresses across routers, so the broadcast address does not need to be set in the link command of the llttab file.

```plaintext
set-node Node1
set-cluster 1

link link1 udp - udp 50000 - 192.1.3.1 -
link link2udp - udp 50001 - 192.1.4.1 -

#set address of each link for all peer nodes in the cluster
#format: set-addr <node-id> <link tag-name> <address>
set-addr 0 link1 192.1.1.1
set-addr 0 link2 192.1.2.1
set-addr 2 link1 192.1.5.2
set-addr 2 link2 192.1.6.2
set-addr 3 link1 192.1.7.3
set-addr 3 link2 192.1.8.3

#disable LLT broadcasts
set-bcasthb 0
```
Configuring LLT over UDP

Sample configuration: Links crossing IP routers

```
set-arp 0

The llttab file on Node 0 would resemble:
set-node Node0
set-cluster 1

    link link1 udp - udp 50000 - 192.1.1.1 -
link link2 udp - udp 50001 - 192.1.2.1 -

#set address of each link for all peer nodes in the cluster
#format: set-addr <node-id> <link tag-name> <address>
set-addr 1 link1 192.1.3.1
set-addr 1 link2 192.1.4.1
set-addr 2 link1 192.1.5.2
set-addr 2 link2 192.1.6.2
set-addr 3 link1 192.1.7.3
set-addr 3 link2 192.1.8.3

#disable LLT broadcasts
set-bcasthb 0
set-arp 0
```
Issues and Limitations

The following issues and limitations apply:

**VCWSilent does not support LLT over UDP configuration**
VCS provides a silent configuration utility, VCWSilent.exe, that can be used to configure a new cluster. However, the VCWSilent does not support configuring LLT over UDP.

**VCW does not support configuring broadcasting for UDP**
VCW does not provide options to configure broadcasting information for UDP. You can configure broadcasting for UDP by manually editing the llttab file, as described in this appendix.

**If the network adapters are unable to ping each other, the cluster nodes may not get GAB membership**
While configuring LLT over UDP, if the network adapters selected for the LLT communication are unable to ping each other and you proceed with the cluster configuration, VCW configures the LLT service on the selected network adapters but the cluster nodes may not receive GAB membership and as a result the Veritas High Availability Engine, HAD, may fail to start.
You can confirm the GAB membership by running the following command:
C:\gabconfig -a
If no port membership information is returned it indicates that GAB is not operating.
This issue can be addressed in either of the following methods:

Method 1:
1 Reboot the cluster nodes that do not have GAB membership.
2 Verify the GAB operation in the cluster. Type the following on the command prompt:
   C:\gabconfig -a
   If GAB membership information is displayed for all cluster nodes, GAB is working correctly. However, if the appropriate GAB membership information is not returned for one or more nodes, GAB is not operating correctly. In that case, proceed to the next method.

Method 2:
1 Stop the LLT service in the cluster. Type the following on the command prompt:
C:\net stop llt

2. Delete the cluster using VCW.

3. Ensure that the network adapters are able to ping each other and then re-create the cluster using VCW.
Handling concurrency violation in Any-to-Any configurations

- About handling concurrency violation
- Concurrency violation scenario
- About the vcsgensvc.vbs script
- Sample configuration to handle concurrency violation
Handling concurrency violation in Any-to-Any configurations

About handling concurrency violation

This appendix describes how you can use the Process agent, along with a sample script, to handle potential concurrency violation in an Any-to-Any configuration that uses the GenericService agent.

Concurrency violation scenario

Consider the following excerpt from a configuration in which an antivirus software is configured as a GenericService resource in an Exchange service group.

**Exchange Service Group 1**

- System List = \{S1, S3\}
- GenericService G1 controlling "NortonAntivirus"
- ExchServices E1 managing Exchange Information Store, Message Transfer Agent, and System Attendant services
- Lanman ExchVName1 controlling the E1 Virtual server

...  
G1 requires E1  
E1 requires ExchVName1

**Exchange Service Group 2:**

- System List = \{S2, S3\}
- GenericService G2 controlling "NortonAntivirus"
- ExchServices E2 managing Exchange Information Store, Message Transfer Agent, and System Attendant services
- Lanman ExchVName2 controlling the E2 Virtual server

...  
G2 requires E2  
E2 requires ExchVName2

In this example, S3 is the standby system for both S1 and S2. Service Group 1 is online on S1 and Service Group 2 is online on S2. Such a configuration is desirable for an application like Exchange that requires an antivirus service instance attached to it.

Consider a scenario where Service Group 1 fails over from S1 to S3. When G1 comes online on S3, G2 also reports online because both G1 and G2 monitor the same service. As a result, VCS reports a concurrency violation for Service Group 2 from S3 and tries to take G2 offline on S3. As soon as G2 is taken offline on S3, G1 reports a fault, and Service Group 1 faults on S3.

This situation can be addressed by using a custom script along with the Process agent, in place of the GenericService agent.
About the vcsgensvc.vbs script

The script vcsgensvc.vbs resides at the path %VCS_HOME%\Samples\Process. The script works with the Process agent to bring services online, monitor them, and take them offline.

The script takes the following parameters:

Table G-1 vcsgensvc.vbs script parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Accepted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation</td>
<td>online</td>
</tr>
<tr>
<td></td>
<td>offline</td>
</tr>
<tr>
<td></td>
<td>monitor</td>
</tr>
<tr>
<td>Service Name</td>
<td>Display or key name of the service</td>
</tr>
<tr>
<td>Computer Name</td>
<td>The name of the computer (virtual computer being monitored This parameter applies only to the MonitorProgram attribute of the Process resource.</td>
</tr>
</tbody>
</table>
Sample configuration to handle concurrency violation

In the following sample configuration, the Process agent monitors the Norton Antivirus service. The script is installed in the following directory:

D:\Program Files\Veritas\Cluster Server\Samples\Process

The script takes the Exchange virtual server name as an input parameter and monitors the service using this virtual name. If the Exchange Virtual server is online and the antivirus service is running, the script returns ONLINE, instead of returning ONLINE based on the status of the service alone.

Note that this recommendation is for this specific scenario only. The Process agent is not an alternative to the GenericService agent, which offers added functionality for generic services.

For Exchange Service Group 1:

System List = {S1, S3}  
Process AVService1 controlling "NortonAntivirus"  
ExchServices E1  
Lanman ExchVName1 controlling the E1 Virtual server
...

G1 requires E1  
E1 requires ExchVName1
...

Lanman L1 (  
    VirtualName = ExchVName1
)

Process AVService1 (  
    StartProgram = "CScript.exe \"d:\program files\"veritas\cluster server\samples\process\vcsgensvc.vbs\"online NortonAntivirus"
    StopProgram = "CScript.exe \"d:\program files\"veritas\cluster server\samples\process\vcsgensvc.vbs\"offline NortonAntivirus"
    MonitorProgram = "CScript.exe \"d:\program files\"veritas\cluster server\samples\process\vcsgensvc.vbs\"monitor NortonAntivirus ExchVName1"
)

For Exchange Service Group 2:

System List = {S2, S3}  
Process AVService2 controlling "NortonAntivirus"  
ExchServices E2  
Lanman ExchVName2 controlling the E2 Virtual server
...
G2 requires E2
E2 requires ExchVName2
...
Lanman L2 {
    VirtualName = ExchVName2
}
Process AVService2 {
    StartProgram = "CScript.exe \"d:\program files\veritas\cluster server\samples\process\vcsgensvc.vbs\" online NortonAntivirus"
    StopProgram = "CScript.exe \"d:\program files\veritas\cluster server\samples\process\vcsgensvc.vbs\" offline NortonAntivirus"
    MonitorProgram = "CScript.exe \"d:\program files\veritas\cluster server\samples\process\vcsgensvc.vbs\" monitor NortonAntivirus ExchVName2"
}

Notes for using scripts with the Process agent

- In the above example, the supplied script assumes that Service Group 1 and Service Group 2 will never come online on one system. Service Group Workload Management or triggers must be configured to meet this requirement.
- When using this configuration, we recommend setting the user context of the Process agent to LocalSystem.
Handling concurrency violation in Any-to-Any configurations

Sample configuration to handle concurrency violation
Glossary

**Agent**
A process that starts, stops, and monitors all configured resources of a type, and reports their status to VCS.

**Active/Active Configuration**
A failover configuration where each system runs a service group. If either fails, the other one takes over and runs both service groups. Also known as a symmetric configuration.

**Active/Passive Configuration**
A failover configuration consisting of one service group on a primary system, and one dedicated backup system. Also known as an asymmetric configuration.

**Authentication Broker**
The Veritas Security Services component that serves, one level beneath the root broker, as an intermediate registration authority and a certification authority. The authentication broker can authenticate clients, such as users or services, and grant them a certificate that will become part of the Veritas credential. An authentication broker cannot, however, authenticate other brokers. That task must be performed by the root broker.

See “Root Broker.”

**Cluster**
One or more computers linked together for the purpose of multiprocessing and high availability. The term is used synonymously with VCS cluster, meaning one or more computers that are part of the same GAB membership.

**Daemon Down Node Alive (DDNA)**
A situation where the VCS high availability daemon has failed on a system and has not been restarted by the hashadow process.

**Disaster Recovery**
A solution that supports fail over to a cluster in a remote location in the event that the local cluster becomes unavailable. Disaster recovery global clustering, heartbeating, and replication.

**Failover**
A failover occurs when a service group faults and is migrated to another system.

**GAB**
*Group Atomic Broadcast* (GAB) is a communication mechanism of the VCS engine that manages cluster membership, monitors heartbeat communication, and distributes information throughout the cluster.

**Global Service Group**
A VCS service group that spans across two or more clusters. The ClusterList attribute for the group contains the list of clusters over which the group spans.
hashadow Process
A process that monitors and, when required, restarts HAD.

High Availability Daemon (HAD)
The core VCS process that runs on each system. The HAD process maintains and communicates information about the resources running on the local system and receives information about resources running on other systems in the cluster.

Jeopardy
A node is in jeopardy when it is missing one of the two required heartbeat connections. When a node is running with one heartbeat only (in jeopardy), VCS does not restart the applications on a new node. This action of disabling failover is a safety mechanism that prevents data corruption.

LLT
Low Latency Transport (LLT) is a communication mechanism of the VCS engine that provides kernel-to-kernel communications and monitors network communications.

main.cf
The file in which the cluster configuration is stored.

Network Partition
If all network connections between any two groups of systems fail simultaneously, a network partition occurs. When this happens, systems on both sides of the partition can restart applications from the other side resulting in duplicate services, or “split-brain.” A split-brain occurs when two independent systems configured in a cluster assume they have exclusive access to a given resource (usually a file system or volume). The most serious problem caused by a network partition is that it affects the data on shared disks.
See “Jeopardy.”
See “Seeding.”

Node
The physical host or system on which applications and service groups reside. When systems are linked by VCS, they become nodes in a cluster.

N-to-1
An N-to-1 configuration is based on the concept that multiple, simultaneous server failures are unlikely; therefore, a single backup server can protect multiple active servers. When a server fails, its applications move to the backup server. For example, in a 4-to-1 configuration, one server can protect four servers, which reduces redundancy cost at the server level from 100 percent to 25 percent.

N-to-N
N-to-N refers to multiple service groups running on multiple servers, with each service group capable of being failed over to different servers in the cluster. For example, consider a four-node cluster with each node supporting three critical database instances. If any node fails, each instance is started on a different node, ensuring no single node becomes overloaded.

N-to-M
N-to-M (or Any-to-Any) refers to multiple service groups running on multiple servers, with each service group capable of being failed over to different servers in the same cluster, and also to different servers in a linked cluster. For example, consider a four-node cluster with each node supporting three critical database instances and a linked two-node back-up cluster. If all nodes in the four-node cluster fail, each instance is started on a node in the linked back-up cluster.

**Replication**
Replication is the synchronization of data between systems where shared storage is not feasible. The systems that are copied may be in local backup clusters or remote failover sites. The major advantage of replication, when compared to traditional backup methods, is that current data is continuously available.

**Resources**
Individual components that work together to provide application services to the public network. A resource may be a physical component such as a disk or network interface card, a software component such as Oracle8i or a Web server, or a configuration component such as an IP address or mounted file system.

**Resource Dependency**
A dependency between resources is indicated by the keyword “requires” between two resource names. This indicates the second resource (the child) must be online before the first resource (the parent) can be brought online. Conversely, the parent must be offline before the child can be taken offline. Also, faults of the children are propagated to the parent.

**Resource Types**
Each resource in a cluster is identified by a unique name and classified according to its type. VCS includes a set of predefined resource types for storage, networking, and application services.

**Root Broker**
The first authentication broker, which has a self-signed certificate. The root broker has a single private domain that holds only the names of brokers that shall be considered valid. See “Authentication Broker.”

**Seeding**
Seeding is used to protect a cluster from a pre-existing network partition. By default, when a system comes up, it is not seeded. Systems can be seeded automatically or manually. Only systems that have been seeded can run VCS. Systems are seeded automatically only when: an unseeded system communicates with a seeded system or all systems in the cluster are unseeded and able to communicate with each other.

See “Network Partition.”

**Service Group**
A service group is a collection of resources working together to provide application services to clients. It typically includes multiple resources, hardware- and software-based, working together to provide a single service.

**Service Group Dependency**
A mechanism by which two service groups can be linked by a dependency rule.
Shared Storage
Storage devices that are connected to and used by two or more systems.

SNMP Notification
Simple Network Management Protocol (SNMP) developed to manage nodes on an IP network.

State
The current activity status of a resource, group or system.

types.cf
The types.cf file describes standard resource types to the VCS engine; specifically, the data required to control a specific resource.

Virtual IP Address
A unique IP address that associated with the cluster. It may be brought up on any system in the cluster, along with the other resources of the service group. This address, also known as the IP alias should not be confused with the base IP address, which is the IP address that corresponds to the host name of a system.
